Restoration of Heart in Chloroform Poisoning.—It is shown by Ransom in perfusion experiments that frogs' hearts depressed by chloroform may be restored to nearly or in some cases quite normal activity by adding to the chloroform solution small quantities of epinephrin, tyramin, strophanthus, diuretin, caffeine or strontium chlorid (pituitary extract failed). In the case of epinephrin and tyramin, the restored hearts will continue beating well in the presence of toxic amounts of chloroform for some hours. The other substances when added to the chloroform solution cause, first, restoration and then characteristic toxic symptoms of their own, but this latter difficulty may be overcome if, as soon as restoration has taken place, the perfusion fluid is changed to plain Ringer's solution. By this method of giving a small quantity of the antagonist and following with plain Ringer's solution restoration is much quicker than when the chloroform is simply washed away.

Anaphylactoid Phenomena from Intravenous Administration of Colloids, Arsenicals and Other Agents.—Mild ether

anesthesia and the intravenous injection of physiologic sodium chlorid solution are practically harmless to the circulatory and respiratory systems of guinea-pigs, but the remaining twenty-nine of the thirty-one agents studied by Hanzlik and Karsner were found to be distinctly harmful in varying degrees. The results obtained by the authors are decidedly against the promiscuous and unwarranted use of the intravenous method of administering drugs as a routine therapeutic measure, particularly for new and untried remedies or those of doubtful efficacy, and even those which chemically and pharmacologically appear to be inert or inactive. When taken together with the explanations supplemented throughout the text, these results indicate that it is quite erroneous to regard the disturbances produced by the intravenous injection of sundry agents in the same category with true anaphylaxis or bearing any causal relationship to it whatsoever, or vice versa. On the basis of the results obtained with atropin and epinephrin, Hanzlik and Karsner claim that the mechanism of action of agar and similar agents bears no relationship to true anaphylaxis or anaphylactic shock.

Sputum Borne Disease Transmission.—This experimental research shows the facility with which a nonpathogenic organism may be transmitted from donor to recipient through the use of warm mess-kit wash water. The results of these tests, in conjunction with the epidemiologic research, indicate that mess-kit water was the most prolific source of distribution of pathogenic organisms and virus infections among troops. These results are wholly corroborative of the previously advanced theory of transmission through warm mess-kit wash water, and the paramount importance of the use of boiling water as a means of closing the major avenue of disease distribution.

Traumatic Aneurysm.—Of the six cases reported by Flannery and Tormey, three were arteriovenous, one was arterial, one was venous and one was diffuse. Four patients were discharged, cured; one patient died of meningitis, secondary to compound comminuted fracture of skull, and one died of shock, following loss of blood after operation. All vessels involved were ligated following long periods of complete rest, immobilization and pressure over the mass. The period of rest, varying from eleven to sixty-two days (an average of thirty-three and five-tenths days), was sufficient to allow collateral circulation to become fully established, thereby diminishing the risk of postoperative gangrene. The authors insist that it is essential that all clots be removed, thereby relieving pressure on the remaining vessels and lessening the chances of gangrene from the interference of circulation below. Postoperative treatment is very important: (a) The wound should have a large, soft, sterile dressing applied. (b) The extremity should be allowed to lie in its natural position. Splints are contraindicated, as pressure necrosis is apt to occur. (c) No hot-water bags should be used,

except to warm the bed before the patient is returned from the operating pavilion, as sloughing may occur in those parts of the extremities in which collateral circulation is not fully established. (d) If heat is thought necessary to aid the circulation in the extremity, the therapeutic light is advised.

Coating for Poison Tablets to Prevent Accidental Poisoning.—Phillips has developed a coating intended to render poison tablets innocuous when swallowed, but which interferes in no way with their use for making germicidal solutions. The contrivance consists of a coating of wax, the wax having a melting point above the highest climatic temperature, one which is not brittle and, therefore, which will not crack or scale from the tablet in handling; and, above all, which not only is insoluble in water, but is not affected by the digestive juices. Tablets coated with such a wax pass through the alimentary tract unchanged and consequently prevent any solution or absorption of the tablet substance while in the body. By breaking the tablets they may be dissolved readily when it is desired to prepare solutions from them. After many trials during which a large variety of substances has been rejected as unsuitable for this purpose, a coating has been developed which not only satisfies all theoretical requirements but which meets every demand for practicability. By mixing equal parts by weight of candelilla wax and a paraffin having a melting point of 56 C., a wax is obtained which melts at 70 C., which has a low coefficient of expansion and, therefore, little brittleness, which is unaffected by dilute acids and alkalies and which is not attacked by digestive ferments. Furthermore, the device presents no serious difficulties as to the manufacture. The machines employed for coating pills with gelatin are equally well adapted for applying the wax coating to tablets, while the combined cost of the materials and the process for quantity production is negligible. The perfected coating has the added advantages of protecting the tablet from moisture, and from breaking or crumbling in the container. Deterioration is prevented, and exact dosage is assured.

Anaphylactic Reactions in Course of Antirabic Treatment.

—It is suggested by Cornwall that the local cutaneous and subcutaneous tissue reaction, the general dermal reaction, the general systemic reaction in the form of malaise and a reaction of the central nervous system in the form of temporary heart failure, occipital pain and nausea, occurring in the course of antirabic treatment are anaphylactic in nature. The antigen may be either normal brain matter or the products of metabolism of the rabies organism. Attempts to reproduce the central nervous system reaction in rabbits have so far been unsuccessful. Similarly, attempts to demonstrate a state of shock in sheep were without success. In untreated sheep intravenous injections of fixed virus brain extracts caused greater disturbance of the cardiovascular and respiratory centers than extracts of normal brain substance. These disturbances are not invariable whether fixed virus brain extracts or normal brain extracts are injected.

Pharmacodynamics of Quinin.—An experimental investigation made by McCarrison and Cornwall showed that the usual salts of quinin employed for intravenous medication are dangerous to life if given in large doses. The respiratory center is more gravely affected than the cardiac center. The acid hydrobromid is less noxious in its action on the respiratory center than the hydrochlorids of quinin. All the salts of quinin employed caused a profound fall of blood pressure not accompanied by a cessation, or even much diminution in the strength of the heart beat, except in two instances in which the respiratory center failed. The fall of blood pressure is usually recovered from in four or five minutes, but the period of cardiovascular depression may last for a considerable time. The dilution of the quinin with a large volume of salt solution does not compensate for its depressor action: nor does dilution with 6 per cent. gum arabic solution. The authors advise that intravenous injections of quinin should be given very slowly. They should be administered with great caution when the general condition of the patient is bad and when the blood pressure is low. All such injections should be controlled by blood pressure observations. Epinephrin, given intravenously with the quinin, is able to counteract, to some extent, the immediate and dangerous fall of pressure which may result from quinin alone. The intravenous employment of quinin should be reserved for cases of special urgency, and where possible the hydrobromid, in doses not exceeding 15 grains, should be used, and the injection combined with not more than 0.3 c.c. of the commercial solution of epinephrin in all cases where the blood pressure is less than 100 mm. of mercury. These experiments indicate that quinin is a much more poisonous drug than is generally supposed, and that the massive dosage so generally employed today cannot fail to depress, by whatever route administered, the cardiovascular

and respiratory systems, and to retard the development of that natural immunity on which the cure of the disease is dependent.

Transmitting Agent of Bagdad Boils.—From the fact that the Bagdad boil is only found on exposed parts of the body, Acton is led to believe that the transmitting agent is some blood sucking diptera. The distribution of these Bagdad sores corresponds more closely with sandfly bites than with the bites of other blood sucking diptera.

Pathogenesis of Deficiency Disease.—After having made a very detailed study of this subject, the results of which are given in full, McCarrison is convinced that the absence of certain accessory food factors from the dietary—improperly termed "antineuritic"—leads not only to functional and degenerative changes in the central nervous system but to similar changes in every organ and tissue of the body. The morbid state to which their absence gives rise is not a neuritis. The symptom-complex resulting from the absence of these substances, is due (a) to chronic inanition, (b) to derangement of function of the organs of digestion and assimilation, (c) to disordered endocrine function especially of the suprarenal glands, and (d) to malnutrition of the nervous system. Certain organs undergo hypertrophy; others atrophy. Those which hypertrophy are the suprarenals. Those which atrophy, and in the order of severity named, are the thymus, the testicles, the spleen, the ovaries, the pancreas, the heart, the liver, the kidneys, the stomach, the thyroid and the brain. The pituitary gland showed a slight tendency to enlargement in adult male pigeons only. Gastric, intestinal, biliary and pancreatic disorders are important consequences of a dietary too rich in starch and too poor in vitamins; this state is due to the imperfect metabolism of carbohydrates and to acid fermentation of starches in the intestinal tract. Clinically, it is evidenced in pigeons by progressive slowing and deepening of the respirations. Great atrophy of muscular tissue results from deficiency of antineuritic vitamins; it is due, in part, to the disturbance of carbohydrate metabolism in consequence of disordered endocrine function, in part to the action of the suprarenals in supplying blood to the vegetative organs of the body at the expense of the muscles. The central nervous system atrophies little: the paralytic symptoms are due mainly to impaired functional activity of nerve cells; much more rarely to their degeneration. It is thought that because of their atrophy out of all proportion to other tissues the thymus, the testicles, the ovaries and the spleen provide a reserve of accessory food factors for use on occasions of metabolic stress. This reserve, however, is rapidly exhausted. The bones are thinned and there is a loss of bone marrow. The red cells of the blood are diminished by about 25 per cent. The whole morbid process is believed to be the result of nuclear starvation of all tissue cells. Finally, although deficiency of certain accessory food factors is the essential etiologic factor in the genesis of beriberi, it is held that infectious and parasitic agencies may often be important causes determining the onset of symptoms. Vitaminic deficiency renders the body very liable to be overrun by the rank growth of bacteria. It is probable that varying metabolic disturbances may determine the character of these growths.

Treatment of Endameba Dysenterica Infection by Emetin Hydrochlorid.—Eighty cases of *Endameba dysenterica* infection have been treated by MacAdam by a course of 18 grains of emetin, spread over twelve days, 1 grain being given hypodermically and ½ grain orally each day. The endameba of both primary dysenteric attacks and of acute relapses disappeared on the average in one and one-half days; while the average period of persistence of infection in cyst carriers was two and one-half days. The symptoms in the acute cases rapidly disappeared also, their average duration being four days. Eighteen of the eighty cases showed signs of persistent infection during the laboratory examinations. Eleven of these relapses occurred among thirty-six chronic dysenteries. Thirteen of the eighteen relapses occurred within four weeks of the completion of treatment. There was no difference between the time of relapse of acute cases

and of cyst carriers. These results show a considerable improvement on those obtained after a course of emetin by injection alone; while they compare favorably with the results obtained by various workers after full courses of emetin bismuth iodid.

Production of Influenza Vaccine.—Harvey and his associates found that the bacillus of influenza in symbiosis with either *Pneumococcus* or *Streptococcus pyogenes* grows much more luxuriantly than in unmixed culture. The fact of a culture's being mixed is no bar to its use for vaccine purposes, when the mixture contains the components required. The mixed organisms are easily separated by plate methods. The symbiotic method seems to afford a simpler method of obtaining a good yield than the preparation of a complicated medium.

Value of Drugs Used in Treatment of Ankylostomiasis.—The drugs ordinarily used in the treatment of ankylostomiasis were investigated by Wrench and his observations lead him to conclude that the "cures" of ankylostomiasis, so frequently reported and in such large numbers, are not justified in the name, if cure means freedom of the stools from ova. Research is necessary to determine and standardize what is meant by a cure, and then to discover, if possible, a means of cure which is practicable for present purposes. Chenopodium oil is a dangerous drug. In 151 treatments there were thirty-two instances of vomiting, many cases of giddiness and occasionally slight collapse. On nine occasions two capsules only could be given as a treatment and on one occasion one capsule only could be given. Manson's mixture failed to "cure" a single case. Thymol, Wrench says, is superior to Manson's mixture, and inferior to chenopodium oil. As a means of sterilization, thymol is unreliable. The following drugs were also tested in from five to ten cases each: methylene blue, embelia ribes, veronia anthelmintica, butea seeds, various bitters, camphor in combination with menthol and thymol, turpentine, clove oil, peppermint oil, and copaiba. None of these drugs, except turpentine, effected a cure. Turpentine, given in 20 minim doses, three times a day, to seven patients for ten days, "cured" one patient.

Culture Mediums for Growth of B. Influenzae (Pfeiffer).—The two mediums described by Liston were prepared by his assistants, Soparkar and Gore. One medium consists of ordinary nutritive agar mixed with a preparation of human blood. The other medium is almost identical with Mathew's medium.

Bulletin de l'Académie de Médecine, Paris

Jan. 20, 1920, 83, No. 3

- *Lethargic Encephalitis. C. Achard.—p. 67; Idem. Combemale and E. Dubot.—p. 71.
- *Comparative Wassermann Tests. C. Simon.—p. 73.
- Trachoma at Marseilles. Ambaret.—p. 75.
- *Poisonous Mushroom. A. Sartory.—p. 76.

Lethargic Encephalitis.—Summarized in Paris Letter, p. 748.

Comparative Wassermann Test in Blood and Urine.—Simon applied the Bordet-Wassermann test to the blood serum and the urine of 166 syphilitics and 35 healthy persons. The reaction was parallel in both blood and urine in 53 per cent., and it was positive in the urine and negative in the blood in 15 cases; positive in the blood and negative in the urine in 62 cases. The positive reaction in the urine was obtained in larger proportions of cases the longer the interval since infection. It seems rational, he says, that treatment should be continued until the reaction is negative in the urine as well as in the blood and spinal fluid. The findings were constantly negative in the healthy controls except that the urine of one man of 70 gave a positive reaction while the blood serum was negative.

Poisonous Mushrooms.—Sartory warns of the extremely poisonous nature of *Tricholoma tigrinum* Sch., and describes the features of the poisoning therefrom, and means to identify this mushroom. It is particularly dangerous on account of its close resemblance to the edible terreum groups.

Bulletin Médical, Paris.

- *Teaching of Dermatology at Paris. A. J. L. Brocq.—p. 55.
- *Anaphylaxis from Pancreas Insufficiency. M. Nathan.—p. 59.

Teaching of Skin and Venereal Diseases at Paris.—Brocq comments on the danger that either dermatology or venereology will predominate, to the practical exclusion of the other, when there is only one chair for both, as is the case at Paris. He mentions Fournier's incumbency as an example.

Anaphylaxis from Pancreas Insufficiency.—Nathan cites Lesné's experimental research which demonstrated that egg albumin injected into a sensitized animal induced anaphylaxis even after it had been digested with pepsin. But when the egg albumin had been subjected to the action of pancreatic juice, there were no signs of anaphylaxis. This experimental experience has been duplicated in a clinical case, Nathan here reports, in which a boy of 8 had always had diarrhea, rash and eruptions after eating eggs or any dish made with eggs. Examination of the stools showed defective functioning of the pancreas, and the child was given 40 cg. of pancreas extract daily, and dishes made with eggs and gradually whole eggs were added to his diet, with no further signs of intolerance. Whenever the pancreas extract was dropped, the symptoms of anaphylaxis reappeared, but under pancreas extract treatment conditions have been kept normal during the two years to date. Lesné has had a similar experience, the child finally outgrowing the tendency after a few months and not requiring the pancreas treatment further. When the stools show incomplete digestion of muscle fibers, this may give the clue to successful treatment of a certain class of cases of alimentary anaphylaxis.

Jan. 24, 1920, 34, No. 5

- *Lethargic Encephalitis. D. Denéchau.—p. 69.

Lethargic Encephalitis.—Denéchau remarks, in commenting on the four cases in his own practice, that the mortality was 37 per cent. in the twenty-nine cases reported at the Société médicale des hôpitaux. Only nine survived of the eighteen cases followed to date, and four were left with contractures or uncertain gait, ptosis or persisting somnolency. Only five seemed to have recovered completely by the third or fourth month. One died in his own four cases, and one, ten months later, still has paralysis of the two internal rectus muscles, tremor, and cerebellar disturbances in gait, etc. The others, seen last at the fifth month, still displayed numerous sequelae. Dieting and hygiene are the main reliance, but Netter and Lhermitte have reported good results from hexamethylenamin by the vein and by the mouth, with repeated lumbar puncture aiming to draw the drug into the subarachnoid spaces.

Journal de Médecine de Bordeaux

Jan. 25, 1920, 91, No. 2

- *Disability after Injury of the Skull. H. Verger.—p. 31.
- *Tardy Tetanus. H. L. Rocher.—p. 37.
- *Sudden Death after Fracture of Long Bone. R. Villar.—p. 43.
- Clinical Pictures with Trauma of the Brain. H. Duret.—p. 52.

Disability After Injury of the Skull.—Verger enumerates the different forms of permanent disability after trauma of the brain, and their evaluation from the pension standpoint. When the disturbances are vague and are of the concussion type or traumatic neuroses, the majority recover in time. Preexisting syphilis, atheroma, or alcoholism, reducing the resisting powers and providing points of lesser resistance, form another group in which the evaluation of the disability is more difficult. The courts here go farther than medicine can follow. They assume that the traumatism must be incriminated for the disability, as when parietic dementia develops in a syphilitic after an accident, if the medicolegal experts are unable to affirm positively that the parietic dementia would have developed without the trauma. The medicolegal expert thus has his task reversed: Instead of establishing the presumption between cause and effect, he has to seek for proof to the contrary.

Tardy Tetanus.—In Rocher's seven cases the tetanus developed from seventeen to sixty-four days after the wound and

two injections of antiserum. They teach that preventive antiserotherapy should be kept up until all the scraps of foreign bodies have been removed.

Sudden Death After Fractures.—Villar excludes fat embolism in his three cases of death after fracture of long bones, as fat embolism is so rare. Even with the extensive fractures of the war and curetting the marrow cavity, fat embolism very seldom occurred. It develops also in the first few days, and death does not follow until several hours after the first symptoms. The robust men in his cases died in from five to fifteen minutes after the fractured right tibia and fibula had been examined and the callus palpated, or the man had been sitting up in bed to wash his face. Embolism from thrombosis would explain the fatal phenomena. They warn that thrombosis should be suspected in all cases of fracture, especially when the edema persists, and the possibility of embolism therefrom should guide the management of the case.

Journal de Radiologie et d'Electrologie, Paris

December, 1919, 3, No. 11

*Technic for Radium Treatment. C. Regaud and R. Ferroux.—p. 481.

*Radium Emanations in Ampules. S. Laborde.—p. 501.

*Roentgen-Ray Treatment of Pituitary Tumors. M. Jaugeas.—p. 508.

Practical Notes and New Instruments. Strohl and others.—pp. 516-519.

Technic and Record of Radium Treatment.—Regaud and Ferroux are in charge of the *Institut du Radium* at Paris which lends out radium tubes, and they emphasize the importance of a uniform style of record for all radium work. The quantity or dose is the product of the intensity multiplied by the time, but greater precision is realized when the dose (with radium emanations) is calculated from the millicuries lost during the application, that is, the difference between the millicurie power of the tube before and after. With radium itself, by the loss in emanations, that is, the emanations destroyed in the course of an hour (calculated by multiplying the weight in milligrams by the constant 0.00751). The filter, the area exposed, the distance, etc., must be recorded separately.

Condensed Radium Emanations.—Laborde is in charge of the radium service at the Hôpital Villemin, and he reports his experience with radium emanations in closed ampules. Of course they cannot compete with radium itself, but they have many advantages, especially that they can be supplied in any shape to fit any lesion, as in the form of a number of fine needles to be driven into a deep neoplasm. He has found that the annoying feature of the progressive loss of energy when emanations were used was often counterbalanced by the lesser risk from loss of the capsule.

Radiotherapy of Pituitary Tumors.—The death of Jaugeas was reported recently. He said in this article that the action of the roentgen rays can be estimated with greater precision in the effect on a tumor in the hypophysis region than in any other field of application of deep irradiation. The changes in the visual field parallel the benefit otherwise, and form a gauge for the efficacy of the treatment. He describes a case of tumor in the pituitary with acromegaly in a woman of 25. The history of the case is shown by the charts of the field of vision at one and two year intervals, the visual acuteness finally approximating normal. Similar findings in another case rayed in 1914 show that the benefit has been permanent, so that the term "cure" is not out of place applied to such cases. The visual acuity is even better now, five years later, than when the patient was first dismissed. The acromegaly has not retrogressed, but it was arrested. Roentgen-ray treatment in these cases has to be applied early, when symptoms of hyperactivity become manifest, before the elements of the gland are destroyed. The raying must be cautious, to refrain from destroying the functional elements, as otherwise symptoms of deficiency would follow, analogous to experiences with the thyroid. The pulse in exophthalmic goiter and the visual field with pituitary tumors should be the guide to treatment. It should be suspended when these findings enter a stationary phase. It can be resumed if headache and impairment of vision indicate a

new *poussée évolutive*. The exposures should thus be given and suspended according to the individual findings from week to week, without any arbitrary regularity.

Lyon Médical

Jan. 25, 1920, 129, No. 2

*Dissociated Retention of Elements of the Bile. L. Bouchut and Lamy.—p. 53.

*Radioscopy in Diagnosis of Tuberculosis. A. Dumas and A. Corone.—p. 61.

Dissociated Retention of Bile Elements.—Bouchut and Lamy explain the progressive jaundice in the case they report as the result of injury of the liver cell itself. The urine abounded in bile pigments but no bile salts were found in it, while the stools were clay colored and there was nothing at the time or in the history to suggest gallstones. Hemolytic jaundice could also be excluded, but there were indications of alcoholism, and necropsy confirmed the liver disease, revealing cirrhosis of the hypertrophic, alcoholic type in the woman of 47, a cook. They describe how the conception of dissociated elimination of the elements of the bile throws light on a number of clinical pictures in which jaundice is a prominent symptom. Nothing but defective secretion or excretion in the liver itself will explain dissociated retention. Lyon and others have confirmed this experimentally with phosphorus, and with injection of cytotoxins acting on the liver. By thus electively injuring the liver cells, they induced dissociated retention just as it is observed in the clinic.

Radioscopy in Tuberculosis.—Dumas and Corone summarize their conclusions from roentgen-ray examination of 2,000 men suspected of pleuropulmonary tuberculosis at Saloniki in 1918. They emphasize that there is no pathognomonic picture, and that the greatest value of radioscopy is when the findings are negative. In the established cases, it yields important information as to the extent, evolution, etc., and in dubious cases may reveal a lesion when auscultation is negative.

Paris Médical

Jan. 10, 1920, 10, No. 2

*Rating Disability. R. Van Roy.—p. 37.

*Catarrhal Jaundice. E. Chabrol and J. Dumont.—p. 41.

*Urticaria from Emetin. R. Savignac and A. Alivisatos.—p. 43.

*Hemoglobin Reactions. L. Boyer.—p. 47.

Rating Disability.—Van Roy discusses the standards adopted by the French government and Belgium, and shows certain inconsistencies in the figures for the fingers and metacarpus.

Familial Epidemic of Catarrhal Jaundice.—The three cases in the family indicated an unmistakable infectious origin. A few spirochetes were found in the urine of one child but not in the others. The spirochetes did not show the characteristics of the icterohemorrhagiae type, and serologic tests were negative, as also with all other micro-organisms which have been incriminated in the etiology of infectious jaundice.

Emetin Urticaria.—Savignac found emetin in the urine up to three months after the last injection, and hence thinks there can be no doubt that it was responsible for the urticaria which developed fifteen days after some of the later injections, subsiding as they were suspended and returning on resumption of the drug. The urticaria at first was in the region of the injections but later became symmetrical and finally general. The last attack of urticaria occurred five months after the close of the emetin course (1919) and there has been no recurrence since. During the course there was also an attack of neuritis in one arm, but the chronic dysentery seemed to be finally cured by the treatment which had been continued at intervals for nearly a year.

Hemoglobin Reactions.—Boyer describes a number of reactions with hemoglobin and peroxidases with various stains, and commends particularly for detection of blood a mixture of diamino or triaminotriphenylmethane, sodium acetate, acetic acid, and zinc. The reaction is based on the peroxidizing faculty of oxyhemoglobin or its derivatives, and avoids the errors with other reactions of the kind.

- *Treatment of Puerperal Infection. F. M. Cadenat.—p. 33.
*Tuberculosis of the Spine in Adults. J. Doche.—p. 35.

Vaginal Hysterectomy for Puerperal Infection.—Cadenat asserts that too many women die from puerperal infection. Aside from the fulminating fatal cases, there are many, he declares, that might be saved by early vaginal hysterectomy, and he describes with illustrations the exact technic for this, saying that it takes only from three to fifteen minutes in experienced hands; avoids contamination of the peritoneum, and insures ample drainage. It should be done whenever there is no appreciable improvement in twenty-four hours after clearing out the uterus with the curet, the temperature keeping high, with chills, and the pulse fast. The fear of injuring the bladder should not deter from the operation. It is better to have the patient live, even with a vesicovaginal fistula, than die because we are too timid to remove the focus of the infection.

Pott's Disease in Adults.—Doche found no tenderness on pressure in about 33 per cent. of thirty-one cases of caries of vertebrae in the dorsal region, and in 25 per cent. of 102 in the lumbar region in his 140 cases of Pott's disease in soldiers. Many of the men had been treated for months and even years for neuralgias of different kinds, gastralgia, kidney and liver colic, sciatica and torticollis, before any one had thought of incriminating the spine. Lateral curvature was evident in thirty of the 140 cases, and two thirds of the men were unable to bend the trunk forward or sideways, but not one of the total number was able to stretch his spine; hyperextension was absolutely blocked. All were given the regular helio-marine course of treatment at the sanatorium in his charge at Arcachon, and all without fistulas recovered, while the mortality was high among the men with infected fistulas. A tragic feature was that, among the forty-three with fistulas, in some they had been deliberately induced by opening up a closed and cold abscess in the iliac or lumbar region. The strain and privations of the war had reduced the vitality, but notwithstanding this the results of treatment were uniformly good when there was not some grave tuberculous lesion elsewhere or a spontaneous or operative fistula. Immobilization was with a cast in two parts. The front part was removed for the general sun bath; then it was replaced and the patient turned over, and the posterior part of the cast removed for exposure to the sun anew. Thus the sun baths were total while the immobilization was complete throughout. The neuralgic pains were not modified by the heliotherapy, and sometimes they compelled extension. All were kept reclining until six or eight months had elapsed since the last clinical symptoms. The abscesses were punctured; spontaneous resorption was very rare. In the cases with infected fistula, ample drainage and irrigation by the Carrel-Dakin method seem to offer a promise of better results, but his experience with this is too recent for a decisive judgement.

Tumors in the Omentum.—Aimes classifies thirteen varieties of tumors found in the greater omentum, citing cases from international literature, and discussing the symptoms. The malignant tumors are large and very vascular by the time they reach the surgeon, and 25 per cent. of the patients succumbed to the operation, and only two lived for over a year. All forms of omental tumors demand prompt operative removal, he reiterates.

*Sequence of Psychopathologic Phenomena. R. Benon.—p. 531.

Atrophy of Muscle from Concussion.—The shell concussion without direct injury was followed by complete muscular impotency for three months, and muscular atrophy developed and became generalized, but it has gradually receded in the course of the years.

Tender Points in Neck with Abdominal Disease.—Cade and Parturier report experiences which seem to show that the point in the neck where several nerves are accessible to pressure becomes tender when there is some painful pathologic condition in the upper region of the abdomen, on that side. This tender point on the right side coincided with painful disease in liver or gallbladder, especially from gallstones. When the tender point was exclusively or predominantly on the left side, it coincided with painful disease in the stomach or duodenum. In some of the cases reported, the organic lesion was an ulcer or cancer or cicatricial stenosis with fibrous bands. The tender points in the neck may be found with neuralgia or other nervous affections, but in these conditions the tenderness is bilateral and alike on both sides, and it subsides under atropin. The absence of the tender point does not exclude organic disease, as the causal lesion may be in a period of remission, even with a gastric cancer. The point in question is at the base of the neck, between the two heads of the sternocleidomastoid muscle. Several nerves pass here, and the cervical ganglion is anchored in the depths. Among the twenty-nine persons tested, the point was never tender with simple ptosis or simple enlargement of any organ.

Slow Endocarditis.—Debré here concludes his long report of his study of malignant endocarditis running a protracted course. The streptococcus in the blood settles on an already damaged endocardium, and the third phase of the disease is characterized by macroscopic and microscopic emboli which cause various symptoms in different organs. No treatment to date has displayed any durable efficacy, drugs, vaccines, etc. The only case of a cure on record was reported by Hemsted in the *Lancet*, Jan. 4, 1913. He combined an autovaccine with an antiserum obtained from horses immunized with the patient's own streptococci. This seems to be the only line which offers any chance of success. Debré's own experiences with it were failures, but better results may be anticipated when treatment is begun in an earlier stage.

Maternal Serotherapy in Hemophilia.—Chalié proclaims that serum from the mother's blood is the most effectual treatment known to date for congenital hemophilia. He applied it to a youth of 17 who from birth had been subject to hemophilia, and it was growing constantly worse. The mother's serum caused the son's blood to coagulate normally in the test tube, and he was given eleven intravenous injections of from 25 to 40 c.c. of the mother's serum in the course of eleven months. There was never any local or general reaction, and the young man's condition is now more favorable than at any time in his life. Chalié declares that this success encourages systematic infusion of maternal serum every tenth or fifteenth day, kept up for two years at least. In the present case the treatment was not as regular as he wished, owing to the distance from the home. The mother came to him to have the blood drawn, and the next day he took the serum to the patient for injection.

Significance of Sequence of Psychopathologic Phenomena.—Benon reports two cases in which the patients' introspection aided in the clinical and practical study of the pathologic condition, showing the succession and connection between the psychopathologic phenomena.

Pathologic Anatomic Findings in Prognosis of Mammary Cancer.—Iselin reviews the literature on the ultimate fate of breast cancers classified according to their histologic structure, and discusses the conflicting presumptions as to the prognosis based on the pathologic anatomic findings. In his own experience with recent reexamination of 102 patients with mammary cancer given both operative and roentgen-ray treatment, all but 4 of the 27 patients with scirrhus cancer had died within five years, while of the 56 with simple hard cancer 33 per cent. were living after five years and more, and 10 per cent. were alive from ten to fifteen years later. Of the 13 with medullary cancer, 66 per cent. survived for from five to sixteen years. Scirrhus cancers grow slowly and cause so little disturbance that they do not reach the surgeon until far advanced, while with the other forms of cancer the interval between detection and operation was only from a few weeks to three months at longest. The small cells of the scirrhus spread in all directions almost continuously, and thus involve the regions around more readily than other cancers. In all the cases in which there was long survival, the cells had been large, but in a few of the early fatal cases the cells had also been large, so that this is not the only factor in the prognosis. The fact that so many of the irradiated—even of those with involvement of the farthest glands in the supraclavicular fossa—survived for longer intervals is impressive testimony to the value of postoperative irradiation. Even without a radical operation or roentgen-ray treatment he has had survivals up to nine years. In one case the medullary cancer was excised, but the glands were involved to such a distance that no attempt was made to clear out the supraclavicular fossa, and no roentgen exposures were made; but the woman has been in perfect health during the thirteen years since. On the other hand, he has seen cases in which as late as nine years after both excision and roentgen exposures, internal metastasis and recurrence developed.

Actinomyces.—Odermatt has met with a number of cases of actinomycosis of the mouth which had been mistaken for a dental affection; teeth had been drawn, etc., to no avail. Sleeping on straw or hay is a frequent mode of contamination, although the lesions may not become manifest for months up to two years afterward. He describes eight cases in soldiers in which this etiology was evident; in one case the incubation had been eight months long. Schlegel found that the dry spores germinated even after 238 hours of exposure to sunlight. The neck, jaws and the cheek are the most frequent localizations of the lesions, and toothache and swelling are among the first symptoms.

Salt Diuresis.—Pollag recalls that sodium chlorid has long been known to have a powerful diuretic action, and he has been using it systematically for this purpose as a last resort in advanced nephritis. The mechanism, he explains, is like that with ingestion of a single large amount of water in oliguria. It induces such a freshet that the kidneys are flushed open and may stay open. We have no means of knowing, however, which cases will respond favorably to this and which will only be aggravated by it. The same is true of the salt treatment. It is a last resource in desperate cases, seeking to modify conditions with a substance that is not alien to the organism, and which may induce the resorption of edema from heart disease. Four cases showing striking benefit are reported; all the patients had been for some time on a salt-free diet. In one case he believes that it saved the woman's life, transforming a menacing subacute nephritis into the second stage of chronic nephritis, with good concentration and compensation. The woman had taken 15 gm. salt in one day, and the diuresis increased from 250 or 600 to 1,500 c.c., and then to more than 3,750 c.c., for a month, while the edema subsided and the weight dropped by 15 kg. Pollag adds that when no benefit has been realized by abstention from salt, giving a single large amount of salt during one day or three days during the week may jolt conditions back to approximately normal. There were never any untoward effects in his cases, such as have been observed with the "water freshet jolt" but of course such are theoret-

ically liable to occur. No other treatment was being given at the time in his cases.

Urine Test for Tuberculosis.—Debré and Paraf criticize Wildbolz' article on this subject (summarized in these columns, Aug. 9, 1919, p. 456) and Wildbolz replies.

Cicatricial Stenosis of Larynx. E. Aievoli.—p. 984.

Infusion of Sugar Solution.—Zagari reproduces the ergograms and other records of a number of patients with post-malarial anemia, chlorosis or movable kidney, after subcutaneous injection of an isotonic solution of glucose. The record of the muscular exertion showed considerable increase after each injection and more after a series. There was usually a general and febrile reaction by the next day after the first injection but not after the others, and no other by-effects were noted. The output of urine increased after each injection and kept high for some days after suspension. The dose was from 500 to 700 c.c. of a solution of 47 gm. glucose with distilled water to 1,000 c.c. The improvement in energy and the diuresis that followed suggest the wisdom of substituting glucose for sodium chlorid in the so-called physiologic solutions, even when there is no special reason for dropping salt.

Orbital Cysts.—Cavaia's case represents, he says, the first instance of a congenital orbitopalpebral cyst in which the entire eyeball was represented by the cyst.

Acetonuria from Fatigue.—Azzi found an average elimination of acetone bodies amounting to 0.0136 gm. in the twenty-four hours in a healthy man in the ordinary conditions of life. After becoming much fatigued, the amount increased to 0.9 and even 1.44 gm. and on repeated fatigue to 2.5 gm. The tests were made on himself during three weeks of mountain climbing. The ammonia content and the acidity of the urine varied irregularly, but the increase in the acetone output paralleled regularly the exertions inducing fatigue. The acetonuria persisted as long as the sensation of fatigue lasted, disappearing when he felt completely rested. The presence in the blood of the acetone bodies generated during the extra physical exertion is therefore probably one of the causes of the sensation of weariness.

- *Child Welfare Work in Argentina. M. Avila Méndez.—p. 550.
- *Breast Milk Given Out at Milk Station. E. Gaing.—p. 569.

Meningeal Mask of Acute Nephritis.—Bonaba relates that two children were brought to the hospital on succeeding days with symptoms of meningitis, in a comatous condition. The disease had begun five days and fifteen days before, with headache, fever, and edema, and one had had convulsions the last night. The spinal fluid was normal, but the urine showed casts and other signs of nephritis. On restriction to milk both children rapidly recovered. This meningeal mask of the acute nephritis, and the coincidence of the two cases were striking features, as also the independent development of the nephritis.

Infantilism.—Carrau incriminates thyroid deficiency as responsible for the infantilism in one of the two cases he describes, and polyglandular deficiency in the other. Both of the patients, in body and mind, seem very much younger than their actual age (13 and 17). Thyroid treatment or polyglandular treatment seems the only hope in such cases.

Death After Spinal Puncture with Cerebral Cyst.—Ponce de León applied lumbar puncture to clear up a puzzling case of headache and vomiting in a boy of 11. The headaches had begun three months before, and the child preferred to lie down all the time. In the last six weeks the headache had grown worse, especially at night, and vomiting was frequent, and there was hypertonicity and also exaggeration of the reflexes. The region of the frontoparietal sutures was tender, and the legs were somewhat stiff but there was no paralysis. Lumbar puncture released 10 c.c. of normal fluid, but a few hours later the headache became intense and the child died, just twelve hours after the puncture. Morquio recently cited a very similar case in which he refrained from lumbar puncture, but the child died in this same sudden way.

Little's Disease.—The mind seems normal in the young child with congenital spastic paraplegia whose case is described by Berro and Piaggio. The child was born prematurely, and they ascribe the paraplegia to this fact, the pyramidal tracts not having had time to reach their full development.

Tuberculous Pericarditis in Typhoid.—Ponce de León witnessed the development of a primary tuberculous pericarditis which passed into a chronic phase in the girl of 10. It first appeared during convalescence from typhoid fever. The liver was also enlarged but there was no ascites, the clinical picture suggesting Hutinel's tuberculous cardiohepatic cirrhosis. Until ascites develops this may often escape detection.

Defective Development in Inherited Syphilis.—Zerbino gave specific treatment to an infant that seemed normal at birth and thrived on breast milk at first. Then it began to show digestive disturbance and lose weight. Under specific treatment it began to thrive again, even on artificial food. Even with negative Wassermann reaction, he says, the possibility of this *distrofia heredo-sifilitica* should be borne in mind whenever an infant does not seem to be thriving and yet no other cause for this can be discovered.

Meningitis with Pneumococcus Invasion.—Bonaba emphasizes the importance of disinfection of the nasopharynx in cases of meningitis, as otherwise the pneumococcus may invade the meninges as in the child described. Netter suggests adding a little antipneumococcus serum to the antimeningococcus serum. Twenty-two cases are on record in

which the pneumococcus invaded the meninges in the course of meningococcus meningitis.

Child Welfare Work in Argentina.—Avila Méndez describes the organization, development and functioning of the various *institutos de puericultura* and the dispensaries for sick and for well babies.

Distribution of Bottled Breast Milk.—Gaing expatiates on the advantages of distribution of breast milk, saying that the *Instituto de Puericultura Güemes* thus distributed over 4,000 bottles of breast milk in 1917 and nearly 3,000 in 1918. This practice was begun in 1914, and long since demonstrated the transcendent importance of this supply of human milk from healthy women under medical supervision.

- *Arrhythmias. Pablo M. Barlaro.—p. 210. Cont'n.

Ascites with Inherited Syphilis.—Bonorino and Carulla report the case of a man of 39, a hard drinker, who developed venous cirrhosis of the liver with a stormy onset and rapid ascites. There were evidences of inherited syphilis and the ascitic fluid was milky. The duodenal contents seemed to be normal, confirming further the syphilitic nature of the cirrhosis, and it promptly subsided under specific treatment, as in a second case with similar alcoholism and inherited syphilis. The alcohol had reduced the resisting powers of the liver and allowed latent syphilis to flare up and settle here. These experiences, they remark in conclusion, emphasize the importance of giving specific treatment a trial at least in all cases of cirrhosis of the liver of the atrophic type. It has often failed to relieve, but in many cases the benefit amounted to a practical cure.

Tertiary Syphilis of the Liver.—Carretti enumerates the various clinical pictures which may be induced by tertiary manifestations of syphilis in the liver. The examples he cites show that the clinical pictures with either inherited or acquired syphilis may resemble those of all the known types of liver disease and also of disease of organs in the vicinity of the liver. Tentative specific treatment should be instituted, he insists, in every case of liver disturbance in a person with or suspected of inherited or acquired syphilis, and also in every case of cancer of the liver with an unfavorable prognosis even where there is nothing to suggest syphilis. Among the personal cases reported, is one in which a supposed hydatid cyst in the liver vanished under mercury and iodid; the man of 30 had certain stigmata of inherited syphilis.

- *Low Blood Pressure in Typhoid. R. Sanmartín L.—p. 148.

Low Blood Pressure in Typhoid.—Sanmartín noted unusually low blood pressure in six recent cases of typhoid. Assuming that the suprarenals were suffering from the disease, he gave a 1:1,000 solution of epinephrin to supplement their deficient functioning. The output of urine decreased during the low pressure period but returned to normal after the epinephrin was given. Five drops every three hours were given at first and then 5 or 10 drops daily to keep the pressure normal. In one very grave case, 10 drops were given four times one day by the mouth, and later 40 drops were injected subcutaneously, with a maintenance dose of 30 drops by the mouth daily, and camphorated oil was injected daily after the seventh day as the blood pressure dropped dangerously when drugs were suspended. The blood pressure in this person was normally very low, which explained the peculiarly grave situation during the typhoid. All the six patients recovered; in the one case with a six day relapse the tenth day after defervescence, no effect on the blood pressure was apparent then from the epinephrin.

- *Radiologic Diagnosis of Appendicitis. R. Duque Estrada.—p. 827.
- *Prophylactic Serotherapy for Parturients. H. García San Martín.—p. 834.
- *Epidemic and Tuberculous Meningitis. L. Morquio.—p. 847.

Roentgen-Ray Diagnosis of Appendicitis.—Duque Estrada has examined with the roentgen rays over 2,200 cases in which appendicitis was suspected, and relates that the findings were instructive except in the acute cases. Here they served merely to eliminate displacement of the cecum as responsible for the disturbances. The diagnosis of appendicitis cannot be reduced to an algebraic formula that pain at McBurney's point = appendicitis. Many other factors must be taken into account, including the shape, mobility, and time of evacuation of the appendix. The roentgen picture cleared up the diagnosis in 60 per cent. of his cases.

Prophylactic Antistreptococcus Serum for Parturients.—García has been making a practice of injecting from 20 to 40 c.c. of antistreptococcus serum in every woman entering the maternity in labor. A series of 100 parturients, all in exclusively physiologic conditions, and all injected with the antiserum, are compared with 100 absolutely analogous cases but without the antiserum. He was amazed to find that the number of cases of puerperal infection was nearly twice as large (twelve) in the injected series as in the noninjected (seven). He theorizes to explain this, suggesting that the antiserum may have depressed the resisting powers, or induced changes in the depths of the tissues like the urticaria and other superficial phenomena of serum sickness. We know that the antiserum modifies the blood picture, and the reaction may change from the early high leukocytosis to actual leukopenia. Cases have been recorded in which the leukocytosis of 13,640 at first dropped to 2,530 as symptoms of serum sickness developed. The preventive antiserum may thus reduce the organic resistance and actually promote infection, allowing it to get a firm foothold.

Epidemic and Tuberculous Meningitis.—Morquio has encountered twenty-three cases of tuberculous meningitis within little more than a month in children from 6 months to 15 years old, an unprecedented number in such a short period, but all had had influenza from a few days to two or three months before. Some had seemed to be entirely healthy previously. It is not always easy to differentiate it from epidemic meningitis; it may develop suddenly and run a fulminating course, fatal in a week. On the other hand, he has had cases of epidemic meningitis which dragged along with a subacute attenuated course with exacerbations and remissions like those of tuberculous meningitis. But, with the latter, lymphocytes predominate in the limp cerebrospinal fluid, which contains from 100 to 500 elements. With epidemic meningitis, the cerebrospinal fluid may finally assume these characteristics, spontaneously or under the influence of the antiserum. This may lead to the assumption of tuberculous meningitis unless lumbar puncture has previously demonstrated the characteristics of the epidemic form. The differential diagnosis is exceptionally important in these cases, as all depends on the prompt use of the antimeningococcus serum. In a case described, the lumbar fluid at the sixth day of the sickness was turbid and contained innumerable formed elements, polynuclears predominating. Twenty-four hours later the fluid was clear, with only 192 elements, and lymphocytes predominated. This pointed to tuberculous meningitis, but on the basis of the first findings, he injected antimeningococcus serum and the cure was prompt and complete. In another case, likewise at the sixth day, the lumbar puncture fluid was purulent, with 79 per cent. polynuclears, but the next day the fluid was clear, with 480 elements, and 95 per cent. of them were lymphocytes. The meningococcus was cultivated from the fluid and a complete cure followed a single dose of 15 c.c. of the antiserum. He comments on the rapidity of the change in the cerebrospinal fluid, and the liability of mistaking for tuberculous meningitis cases of the epidemic form with clear fluid, with or without polynuclears, and the form with lymphocytosis and rapid recovery. The onset may have been

typical, but by the time the physician sees the case, the clinical picture may have become modified into an abortive, atypical form, difficult to label.

Semana Médica, Buenos Aires

- *Transient Unilateral Amaurosis. P. B. Ferro.—p. 611.

Surgery for Children.—Jorge remarks that it is distressing to hear the parents tell of the conflicting advice they have received from the different medical men they have consulted in regard to congenital defects or acquired deformities of their children. Physicians in general, he says, seem to have such vague and erroneous ideas in regard to them and they allow the deformity to progress, or exaggerate it by some mutilating operation, or merely advise taking the child to Europe or North America. His article is a plea for the founding of a chair of surgery for children and orthopedics at Buenos Aires.

Survival of Fetus when there is no Pulsation in the Cord.—Boero confirms Balard's recent statement that the blood stream may be passing through the prolapsed cord even when no pulsation is apparent in it. The fetal heart can be felt or heard beating on intra-uterine exploration or through the walls. The survival of the fetus can thus be determined, instead of taking its death for granted when the cord ceases to pulsate.

Sarcoma of Eyelid.—The melanic sarcoma had grown from the conjunctiva of the upper lid, and it was successfully removed by Cisneros's *electro-coagulo-ignicion* method, charring a circle of tissue all around the tumor and thus preventing hemorrhage. There were several papillomas on both the upper and lower lid, and all were burnt off by this same method. The sarcoma had developed to a size of 10 by 13 mm. in less than a month after it had first been discovered.

Mishaps with Induced Pneumothorax.—Cetrángolo agrees with Morelli in the assumption that instances of disagreeable by-effects with therapeutic pneumothorax are not always published. The physician should not be too timid nor overconfident in applying the procedure, relying too exclusively on the manometer. In his own extensive experience there have been several cases in which hemoptysis or subpleural and subcutaneous emphysema developed, four of secondary valve formation, and one of gas embolism. Faulty technic was responsible in this latter case; the young man had long been returning weekly for insufflation of 200 or 300 c.c. of oxygen and was doing finely, having gained 10 pounds in weight and the fever having disappeared. As Cetrángolo introduced the needle he felt the usual sensation of having traversed the pleura, but the manometer did not waver. Instead of waiting for the usual fluctuations, he began the insufflation. The patient complained at once of intense precordial pain and numbness in his arm. The needle was withdrawn, but the young man became unconscious after some convulsive movements, with complete arrest of the heart action and breathing. Under artificial respiration, injection of camphorated oil and inhalation of oxygen, he promptly revived but seemed dazed. This and facial paralysis persisted till night, and there was some vomiting. But all was normal the next day and he had no remembrance of the mishap. The lesson from it is that the gas must not be pumped in before the manometer gives the signal. If a little is allowed to enter, it should merely flow in gently. The whole storm passed over in three minutes; probably the fact that oxygen was the gas being used had a great influence on the promptness of the recovery.

The symptoms from secondary valve formation are those of progressive suffocation, an opening allowing the gas to pass, but a valve shutting off its return. Intense pain at the site of the insufflation and progressive dyspnea half an hour to two hours afterward compelled puncture to release the

gas, unless relief was obtained by a spontaneous subcutaneous emphysema. The pressure had increased from 0 to 20 in one of these cases, and the heart was much hampered. The symptoms kept recurring through three days in this case. In all of this group of four the pulmonary lesions were grave and of long standing; the traction on fibrous bands evidently tore out a piece from the parenchyma of the lung during coughing. Hemoptysis was due to pricking a blood vessel, or to activation of the focus in the other lung from traction by bands, or to inadequate compression. In one case described, severe hemoptysis followed insufflation of small amounts of gas, 300 or 500 c.c., but it ceased when the amount was increased, and marked improvement followed.

The Curtain Visual Phenomenon.—Ferro asks for the explanation of the phenomenon he describes which he has encountered in three men of about 50, two of them physicians and all apparently healthy, with normal urine and fundus findings. Once in a while vision seems to be gradually shut off in one eye, and then it gradually returns, the sensation resembling the lowering of the asbestos curtain in a theater.

*The Sachs-Georgi and the Meinicke Reactions. K. Merzweiler.—p. 1273.

*The Rumpel-Leede-Scarlet Fever Phenomenon. H. Müller, Jr.—p. 1275.

*Persistent Salvarsan Exanthems. Dora Fuchs.—p. 1276.

*Remarkable Case of Apparent Death. E. Rautenberg.—p. 1277.

The Origin of Tumors.—Ribbert regards the hereditary factors of all diseases as qualities common to mankind in general, and believes that they are transmitted from one generation to another in the same manner as normal qualities. We must not imagine, he says, that mankind was originally perfectly healthy, but rather assume that from the beginning man was more or less affected by countless anomalies, which, with certain interruptions or skips, manifest themselves in successive generations. We can establish the conditions under which tumors occur, which is as far as we can go with any so-called explanations in the realm of science. A tumor cannot be produced experimentally unless the predisposition thereto exists beforehand, and only so far as such predisposition exists; is it possible for any exciting cause to act on germ cells in such a manner as to cause a tumor to develop. If cancer is hereditary in certain cases, which, in the face of accumulated evidence, can scarcely be denied, it is probably hereditary in all cases. Cancer resulting from industrial contact with pitch, paraffin and arsenic indicates that an external agent sometimes plays a secondary rôle in the development of cancer. This type of cancer suggests also that carcinogenetic deviations from the normal structure of various epitheliums are much more widespread than is commonly supposed, and that by far the majority of the anomalous predisposing germ cells remain quiescent and never develop into cancer. Ordinarily, however, tumors develop "spontaneously" without exciting cause, that is, owing solely to the presence of anomalous predisposing germ cells.

Trauma in Relation to Arteriosclerosis.—While Fraenkel admits that there is no connection between general arteriosclerosis and previous trauma, and still holds fast to the view that sclerosis of the cranial arteries following head trauma is absolutely unproved, he does believe that the case he reports in detail furnishes strong evidence for the assumption that localized sclerosis of the abdominal aorta following trauma does occur. Fraenkel's patient, aged 29, was paralyzed from a gunshot wound of the spine. A year and a half afterward, necropsy revealed changes in the lower segment of the abdominal aorta, which he describes, and which experts declared to be typical arteriosclerosis, but the process was localized exclusively in the region which might easily have been affected by the trauma from the shell wound, a scrap of shell having been found in the lower dorsal cord.

Tuberculosis in Cold-Blooded Animals.—An extensive series of investigations leads Klopstock to the conviction that the tubercle bacillus of man and warm-blooded animals may change into the type found in cold-blooded animals.

The Sachs-Georgi and the Meinicke Reactions.—After examining over 700 serums by the Sachs-Georgi and 366 by the Meinicke method, Merzweiler reaches the conclusion that the Meinicke reaction in its present form cannot be considered an adequate substitute for the Wassermann test. The Meinicke reaction gives a larger percentage of unspecific positive results than the Wassermann reaction. However, Merzweiler found that the Sachs-Georgi reaction, as used in large laboratories where two or three series of tests with fresh extracts are made each week, may be regarded as a complete substitute for the Wassermann reaction. A weak point in the Sachs-Georgi reaction is that it is not reliable when applied to extracts five days old.

Persistent Localized Salvarsan Exanthems.—Fuchs reports the case of a patient who in 1915 was admitted to treatment with a beginning paralysis. Immediately after every neosalvarsan injection (0.45-0.6 gm.) a reddening of the bulbar and palpebral conjunctiva and lacrimation occurred, always in the right eye, disappearing in a few hours. In 1916 the patient was treated with 0.45 and 0.3 gm. of sodium salvarsan, respectively, without any conjunctival reaction. In 1917 there was no unfavorable reaction following repeated sodium salvarsan injections. After 0.45 gm. of neosalvarsan, however, the same conjunctival reaction occurred as in 1915. February 20, 1917, three minutes before the injection of 0.45 gm. of neosalvarsan, 0.5 c.c. of a 1:1,000 epinephrin solution was administered. The reaction of the conjunctiva appeared less promptly and less intensively, and passed off sooner. The patient was then given daily from 1 to 3 gm. of hexamethylenamin and no reaction occurred. February 25, with the same dose of neosalvarsan, the same observations were made as on February 20. September 2, before the injection of 0.45 gm. of neosalvarsan, 1 c.c. of a 1:1,000 epinephrin solution was administered. A very slight irritation of the conjunctiva followed. September 19, after the usual 0.45 gm. dose of neosalvarsan, given four minutes after the injection of 0.5 c.c. of a 1:1,000 epinephrin solution, there was no reaction, confirming the prophylactic importance of epinephrin in warding off side effects from arsphenamin treatment.

A Remarkable Case of Apparent Death.—Rautenberg reports the case of a nurse, aged 23, who, Oct. 27, 1919, took in one dose 1.7 gm. of morphin and 5 gm. of barbital. When found in the park next day, life was almost extinct. She was thought to have died in the ambulance. The indications of death were: rigidity; intense pallor; absence of reflexes, pulse, respiration and heart beat. Hot sealing wax gave no skin reaction. After fourteen hours in the morgue, an official desiring to identify the body, October 29, the coffin was opened. The cheeks had a purplish tinge, and the larynx moved slightly. There were no respiratory movements nor pulse beat, but muffled heart sounds were audible. At 10 a. m. the patient was taken to the hospital. Camphor and caffein were given subcutaneously and stomach lavage was done. A hot bath was given and a flesh brush was applied vigorously, with artificial respiration and oxygen inhalation. At 11 a. m. the pulse could be felt, and short, jerky inspiration was noted. Rigidity of the limbs abated. At 12 the pulse was above 50. October 30, the patient regained consciousness and made a few statements. There were no signs of pneumonia, but persistent leukopenia was present. How is it possible for a human being to live more than twenty-four hours without respiration and blood circulation? Rautenberg explains the strange condition as due to the effect of the narcotic and the cold which, acting together, brought about a paralysis of the vasomotor nerves and thus reduced the needs of the body to a minimum; the narcotic paralyzing the central nervous system, and the cold effecting the rigid paralysis of the organs. He thinks the cold may have prevented rapid resorption of the alkaloid.

The condition was similar to that of hibernation of animals, and this fact tided the organism past the danger of pneumonia.

Deutsche Zeitschrift für Chirurgie, Leipzig

- *Treatment of Pseudarthrosis. H. E. Brunzel.—p. 394.
- *Incarcerated Pectineal Hernia. W. Lehmann.—p. 409.
- *Spastic Ileus. H. F. Brunzel.—p. 414.
- *Salivary Fistula. H. Weitz.—p. 419.

Loose Bodies in Joints.—Hahn analyzes the findings in knee or elbow in eight cases of deforming arthritis and in a number of other joint cases. Her findings confirm the two modes of origin of the loose bodies with deforming arthritis, from a nucleus of cartilage, or of spongy bone tissue. She states that they were always multiple, while the traumatic loose bodies are single.

Treatment of Pseudarthrosis.—Brunzel regards direct injection of tincture of iodine as the most effectual means to induce fibrinous inflammation, and thus accelerate the healing of pseudarthrosis. In his experience with it he injected up to 20 c.c. of the 5 per cent. tincture of iodine (diluted with an equal amount of 96 per cent. alcohol), distributing the fluid throughout the area, depositing some under the periosteum at each end of the pseudarthrosis. In stimulating the healing of fractures and pseudarthrosis which are tardy in consolidating, he has found obstructive hyperemia very useful, but he restricts it exclusively to the site of the fracture. He accomplishes this by applying a close fitting plaster cast with a window over the lesion. The tissues swell up in this window and a localized passive hyperemia results, which he thinks aided materially in hastening the healing. This passive hyperemia is under constant control, the "window tumor" increasing or subsiding as the leg is used, or is raised. This alternation of passive and active hyperemia through the region seemed to be an important factor in the prompt healing in the four cases described. The method did not display the same efficacy when applied to the arms, or to gonorrheal arthritis. The successes were with simple fracture or pseudarthrosis in the legs.

Pectineal Crural Hernia.—Lehmann adds another to the comparatively few cases on record of successful operation for an incarcerated Cloquet hernia.

Laparotomy for Spastic Ileus.—Brunzel's patient was a nurse of 30, of a nervous and hysteric temperament, with repeatedly recurring attacks of ileus, one finally so severe that the abdomen was opened. Nothing pathologic was found, but she supposed that a strangulated loop had been corrected, and she has been free from all disturbances during the five months since the laparotomy to date.

Treatment of Parotid Fistulas.—Weitz reports a case in which he applied Leriche's method of treating chronic salivary fistulas, by resecting the auriculotemporal nerve which presides over the secretion of saliva. In Weitz' case the fistula had persisted for twenty years. The secretion from the fistula stopped at once, and the fistula soon healed.

- *The Attendants on Contagious Diseases. M. Niemeijer.—p. 1873.
- *Fatal Familial Icterus Neonatorum. G. A. Prins.—p. 1880.

Reforms in Medical Teaching.—Van Rijnberk declares that the medical curriculum was planned at a time when the general practitioner was supposed to know something of every branch of medicine, and be prepared to treat everything that turned up. He insists that this is an anachronism now, and he urges that everything should be dropped from the regular medical course except what is basic to all medicine and to all specialties. This would materially lighten the medical course by eliminating everything suggesting any of the individual specialties. The first ten semesters would be the same for all; then the course would branch. The eleventh semester given mainly to obstetrics would entitle to

the degree of general practitioner. Addition of a twelfth, given to gynecology, to the degree of specialist in gynecology. The eleventh and twelfth semesters devoted to roentgenology would give the degree of radiologist. At present, he says, many of those wielding the dangerous rays are like children playing with fire. Other specialties would require the eleventh and twelfth semesters in special studies. He adds that although this plan he knows is a *utopie-fantasie*, yet it has a number of vital advantages, not the least of which is that the patient would be handed over to the specialist at once, the practitioner not only knowing his incompetency but being restrained by law from experimenting in the specialty without the special diploma.

Prophylaxis of Contagious Diseases.—Niemeijer discusses whether it is safe to allow nurses and other attendants in contagious disease isolation hospitals to go to church or mix with people elsewhere during the daily hours off duty. The nurse is in such intimate contact with the patient that the danger of becoming a carrier is much more acute than in the case of any other person, and he is inclined to agree with those who think that with scarlet fever, at least, the nurse should be isolated the same as the patient. A committee of five physicians appointed in his town by the national public health authorities took the opposite view, allowing the nurses to come and go provided extremely strict measures to prevent infection are observed in regard to changing clothing, etc. The committee advise further that a special place in the church should be set apart for them. The only exceptions specified by the committee are smallpox and bubonic plague. In conclusion he cites from a German textbook to the effect that there is no evidence that scarlet fever occurs any more frequently in physicians' families than in the general population.

Familial Icterus Neonatorum.—Prins thinks that nothing but a familial constitutional inferiority of the liver parenchyma will explain the cases related. The woman's first two children were normal but then she met with an accident, falling on her back, and since then the children born were normal at first but by the third day intense jaundice developed. One threw it off in a few days, but a following pair of twins developed the jaundice the third day and both died. The last child also developed the icterus the third day although it seemed otherwise normal in every respect, and it died two days later. The only pathologic finding at the necropsy was an extremely thick and tenacious bile, with bile thrombi in the biliary capillaries, and evidences of phagocytosis in the spleen.

- *The Lesions in a Railroad Accident. J. Fog.—p. 145.

The Injured in a Railroad Accident.—Fog describes the case-histories of forty-five persons injured in an accident, including 4 persons in whom the mind alone was affected; the others required surgical measures. There were 26 with fractures, and 78 fractured bones in the 40 that were killed at once. All the injured complained of intense thirst and cold, but they said they did not feel pain from their injuries. The screaming was from the fright. Meisen compares the lesions and traumatic neuroses with those of the war, saying that the mental condition was exactly like that of shell shock, and also the physical shock seemed to be the same, as evidenced by the pallor, chilliness, imperceptible pulse and mental confusion. The latent period before the mental phenomena developed was also like that observed in the war wounded or shell shocked. He emphasizes the necessity for distinguishing between shock conditions and those from internal hemorrhage.

THE NEW ORLEANS SESSION

AMERICAN MEDICAL ASSOCIATION, SEVENTY-FIRST ANNUAL SESSION
NEW ORLEANS, APRIL 26-30, 1920

OFFICIAL CALL

TO THE OFFICERS, FELLOWS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The seventy-first annual session of the American Medical Association will be held in New Orleans, La., April 26-30, 1920.

The House of Delegates will convene at 10 a. m., Monday, April 26. In the House the representation of the various constituent associations for 1920 is as follows:

Alabama	3	New Hampshire	1
Arizona	1	New Jersey	3
Arkansas	2	New Mexico	1
California	3	New York	11
Colorado	2	North Carolina	2
Connecticut	2	North Dakota	1
Delaware	1	Ohio	6
District of Columbia	1	Oklahoma	2
Florida	1	Oregon	1
Georgia	2	Pennsylvania	9
Idaho	1	Rhode Island	1
Illinois	8	South Carolina	1
Indiana	3	South Dakota	1
Iowa	3	Tennessee	2
Kansas	3	Texas	5
Kentucky	3	Utah	1
Louisiana	2	Vermont	1
Maine	1	Virginia	3
Maryland	2	Washington	2
Massachusetts	5	West Virginia	2
Michigan	4	Wisconsin	3
Minnesota	2	Wyoming	1
Mississippi	1	Canal Zone	1
Missouri	5	Hawaii	1
Montana	1	Philippine Islands	1
Nehraska	2	Porto Rico	1
Nevada	1		

The fifteen scientific sections of the American Medical Association, the Medical Department of the Army, the Medical Corps of the Navy and the Public Health Service are entitled to one delegate each.

The Scientific Assembly of the Association will open with the general meeting to be held at 8:30 p. m., Tuesday, April 27. The Sections will meet on Wednesday, Thursday and Friday, April 28, 29 and 30, as follows:

CONVENING AT 9 A. M. THE SECTIONS ON	
Surgery, General and Abdominal	Pharmacology and Therapeutics
Ophthalmology	Preventive Medicine and Public Health
Diseases of Children	Urology.
Nervous and Mental Diseases	

CONVENING AT 2 P. M. THE SECTIONS ON	
Practice of Medicine	Stomatology
Obstetrics, Gynecology and Abdominal Surgery	Dermatology
Laryngology, Otolary and Rhinology	Orthopedic Surgery
Pathology and Physiology	Gastro-Enterology and Proctology.

The Registration Department will be open from 8:30 a. m. until 5:30 p. m., on Monday, Tuesday, Wednesday and Thursday, April 26, 27, 28 and 29, and from 8:30 a. m. to 12 noon, on Friday, April 30.

ALEXANDER LAMBERT, President.

HUBERT WORK, Speaker, House of Delegates.

ALEXANDER R. CRAIG, Secretary.

MEMBERS OF THE HOUSE OF DELEGATES

A Preliminary Roster of the Legislative Body of the American Medical Association

The list of members of the House of Delegates for the session is incomplete, as a number of the state associations are yet to hold their meetings at which delegates will be elected. The following is a list of the holdover delegates and of the newly elected members who have reported to THE JOURNAL in time to be included:

STATE DELEGATES

ALABAMA		L. F. Woodward, Worcester.
S. G. Gay, Selma.		F. B. Lund, Boston.
F. W. Wilkerson, Montgomery.		E. F. Cody, New Bedford.
ARKANSAS		
R. C. Dorr, Batesville.		
William R. Bathurst, Little Rock.		
CALIFORNIA		
A. B. Spaulding, San Francisco.		
C. Van Zwahlenburg, Riverside.		
Victor Vecki, San Francisco.

THE WHARVES AT NEW ORLEANS

NEW ORLEANS—THE CRESCENT CITY

When the American Medical Association met in New Orleans in 1903, the city was just beginning to feel the good effects of that portion of its new drainage system which began operation in 1900. Today, with this system completed, it is one of the most healthful and attractive cities in the United States. The location, both climatically and commercially, is ideal. The winters are not severe, and while the summers are rather long, the temperature does not reach the excessive heights experienced in summer elsewhere. Sun strokes and heat prostrations are practically unknown. The foliage is such as to indicate that the climate is both temperate and tropical. An analysis of the temperature for the month of April during the last five years indicates a most equable climate:

HIGH, LOW AND MEAN TEMPERATURES, APRIL 20-30, FOR LAST FIVE YEARS

	1915			1916			1917			1918			1919		
April															
20	80	62	71	80	72	76	79	65	72	65	57	61	75	59	67

30	89	70	80	79	58	68	85	69	77	76	65	70	71	63	67

COMMERCE AND MUNICIPAL OWNERSHIP

Municipal ownership has probably been developed to a higher extent here than in any other city in the United States. Among the municipally owned enterprises are the wharves,

covered with steel sheds, Public Belt Railroad, public cotton warehouses, public grain elevators, waterworks, sewerage and drainage, and, in the course of construction, an inner harbor for the location of factories and shipbuilding plants. An enormous amount of money has been expended to make the city secure from inundation from both the river and from Lake Pontchartrain. Rat-proofing has practically been completed at a great expense, and the city has been placed in such physical condition that it will be impossible for any imported pestilence ever again to secure a foothold. Natural gas, which has been found in abundance within less than a hundred miles of New Orleans, will soon be introduced. Since the last meeting of the Association here, the natural resources of Louisiana have come into their own, and have proved to be of such a nature as to make Louisiana one of the richest mineral producing states in the country, particularly for salt, sulphur, oil and gas. Naturally, the timber interests of the state have increased along with other classes, and wonderful fishing and game resources have been developed. The state has been wise in having all of its natural resources under the control of what has proved to be an efficient conservation commission. Available to the visitor are the finest oysters in the world, to be had at any oyster stand or restaurant in the city, and to be eaten with absolute impunity.

SCHOOLS AND UNIVERSITIES

The two principal universities are Tulane and Loyola. Loyola has recently expanded its curriculum extensively, so that, in addition to the ordinary academic courses, it gives courses in some of the special sciences, and has recently established a graduate school of medicine; also certain research laboratories are under way.

TULANE UNIVERSITY BUILDINGS

1. Academic Department, Gibson Hall.
4. Refectory and Physics Buildings.

2. Richardson Chemistry Building.
5. Tilton Memorial Library.

3. Aerial View, Tulane Buildings and Campus.
6. Medical Department, Tulane Campus.

New Orleans has one of the best public school systems in the country, with a great many modern school buildings, both for white and for colored pupils.

TULANE UNIVERSITY

Tulane University of Louisiana during the last fifteen years has developed from a group of loosely coordinated colleges, with varying standards of admission and graduation, into a highly organized university of the first rank. Within this period the attendance has increased from 1,191 in the session of 1904-1905 to 2,500 in the session of 1919-1920; and if we add the summer school, which was begun in 1908, the attendance in 1919 will be 3,762.

Tulane University of Louisiana comprehends the college of Arts and Sciences, the College of Technology, the H. Sophie Newcomb Memorial College for Young Women, the Faculty of Graduate Studies, the College of Law, the College of Medicine, the College of Commerce and Business Administration, and the Summer School. The College of Medicine includes the Schools of Medicine, Pharmacy, Dentistry, and the Graduate School of Medicine (Polyclinic). The College of Technology includes the Schools of Mechanical and Electrical Engineering, Civil Engineering, Chemical Engineering, and Architecture. The H. Sophie Newcomb Memorial College includes, in addition to the usual college course, the Schools of Arts, Music and Household Economy.

During this period the increase in endowment has included only one considerable bequest, for the Newcomb College for Women. There have been within the same period eight buildings erected for educational purposes.

In the past ten years the College of Arts and Sciences has increased its attendance from 96 to 234; Technology, from 164 to 220; Newcomb, from 278 to 537; Law, from 59 to 90; Commerce, from 0 to 681. The School of Medicine, after many variations in attendance due to the raising of standards and fees, and to the effect of the war, has increased its attendance from 355 in 1918-1919 to 416 in 1919-1920.

The College of Technology was organized in 1894. To June, 1919, there have been 440 graduates in technology. Of these, 124 became engineer officers in the late war (2 colonels; 3 lieutenant-colonels; 4 majors; 24 captains and 91 first and second lieutenants and ensigns).

The School of Medicine was established in 1834. To June, 1919, there have been 4,936 graduates. Of these, 578 were in military service in the late war (3 colonels; 11 lieutenant-colonels; 42 majors; 104 captains, and 418 first lieutenants). This school has solved problems in malaria, leprosy, hookworm, pellagra and beriberi, and cooperated in the investigation and eradication of yellow fever. Its students have been coordinated with the Louisiana State Board of Health in training for public health work.

The Tulane Hospital unit was the first base hospital fully organized in the South (mobilized, September, 1917).

During the war session from June 1, 1918, to June 1, 1919, Tulane trained 7,145 students, of whom nearly 5,000 were trained directly for war service.

HOSPITALS

The city has been noted for its true charity, and the most noteworthy of its charities has been the care of the sick. The

Charity Hospital, in the course of its fifty years' existence, has treated gratis, as bed patients, many times more than the present population of 435,000, including many patients from other states than Louisiana. The principal hospitals in the city are, first, naturally the Charity Hospital; then Touro Infirmary, which recently received \$600,000 to be expended in securing added facilities and space, both for their private and free clinic work; the Hotel Dieu; Eye, Ear, Nose and Throat Hospital; the Presbyterian Hospital; the French Hospital; the Illinois Central; Belvedere; the Flint-Goodridge (colored) and Providence (colored), besides a number of private sanatoriums; the City Hospital for Mental Diseases; the Isolation Hospital, and the Louisiana Retreat. Nearly all of these institutions are available for teaching purposes.

THE OLD FRENCH QUARTER

Naturally, with the increase of land values, many of the old buildings have had to give way to improvements. Still, the old French quarter, with its narrow streets and overhanging balconies ornamented with wonderful iron work, retains most of its charm and quaintness, and is a source of great interest and pleasure to the stranger. While ample provision will be made for trips to the various publicly owned institutions and river trips for viewing the harbor, and

while guides will be provided for visitors to the French quarter, the casual visitor may be interested to know that he may, for himself, approximately judge of the age of the buildings he is looking at by the character of the iron work of the balconies. The beautiful wrought iron work denotes that the building is colonial; the cast iron work that the building was constructed some time between colonial days and the outbreak of the Civil War, and all other ornamentation on the building indicates that it was erected after the close of the Civil War. The Civil War fixes the date for

JACKSON SQUARE, THE CABILDO AND CATHEDRAL

the cessation in the use of iron work for ornamental purposes, as all of the foundries at that time devoted their attention to the manufacture of munitions, and, after the war devoted their energies to the manufacture of sugar mills and other implements needed for the material prosperity of the state.

WATER SUPPLY

Prior to 1900, the soil of the city was saturated, always practically to the surface; and prior to 1908 there were no sewers. Vaults and cesspools existed on all premises, and the main reliance for a water supply was on rain water caught from the roof of the houses and stored in wooden cisterns, built on foundations well above ground level. There was a water works system, but not one twelfth of the premises of the city used it at all, and not half of the streets had water mains. Through these mains the natural Mississippi River water (and mud) was available to those who wanted it, but it had to be filtered for almost any use, and hardly constituted a water supply at all.

BEGINNING OF SANITATION

In 1895, the city of New Orleans really started the inauguration of her sanitary improvements by the development of general plans for an effective drainage system. Construction was started in 1897, and was sufficiently advanced by 1900 to begin operation. This at once entirely changed the conditions existing in the well built areas of the city.

THE OLD FRENCH QUARTERS

1 and 2. Old French Court Yards. 3. Dumaine Street, Old French Quarter. 4. Absinthe House. 5. Famous Old French Market

In 1899, the sewerage and water board law was enacted and a tax and plan started for the development of these improvements also, and for the further development of the drainage system. The fund for these uses is a common fund, and the three systems are under a common management. On account of limitation of funds, and the times when they became available, it has been necessary to bring the three systems to their present stage of development gradually.

By 1909, the sewerage and water systems were fully ready to receive connections over the whole built-up area of the city. Since 1909, the drainage system has been greatly enlarged and extended, and the sewerage and water systems have been constantly extended. They have gradually been fully utilized by all of the people, without any legal steps to compel such use, except in the matter of the abolition of a few of the many original roof water cisterns which certain of the citizens wanted to retain for one purpose or another, but which the city desired to eliminate because of the difficulty of preventing the breeding in them of *Stegomyia* mosquitoes, which in the possible event of the importation of a yellow fever case would favor the spread of this disease.

To this time, about \$32,000,000 has been expended on the construction of the sewerage, water and main drainage system, including the cost of water meters, which are furnished on every water connection, and the cost of water and sewerage connections from the mains to the property line. The systems today could not be duplicated for \$50,000,000 and only \$20,000,000 of 4 per cent. bonded indebtedness exists against them.

At present about 600 miles of streets are served with water and sewerage facilities and effective fire protection through fire hydrants at each street intersection, and about 93 per cent. of the premises of the city are connected with the sewers and 96 per cent. with the water works system.

SEWERAGE AND DRAINAGE

New Orleans lies between the Mississippi River and Lake Pontchartrain, which is a slightly brackish tidal lake. One third of the city has its surface elevation at or below mean tide level in the lake, another third has its surface elevation at or below high lake tides in Lake Pontchartrain, and since "tides" in Lake Pontchartrain are the product of prevailing winds acting on the Gulf of Mexico and may be high or low a week at a time and have a range of nearly 7 feet, it is obvious that anything at or below tide level in the lake, depending on a gravity outlet for drainage into the lake, would itself be just a part of the lake. The remaining third of the city is that portion along the bank of the Mississippi River which at various points is naturally from 2 to 8 feet above high tide level in Lake Pontchartrain, and, roughly speaking, from 13 to 7 feet below high water in the Mississippi River. The city, therefore, is protected by substantial earthen embankments, or levees, against inundation both from the lake behind it and from the river in front of it, and is under the necessity of pumping all of its storm water drainage which it discharges into the tidal waters to the rear or to the eastward, because this is the only practical method of getting rid of the vast volume of storm water which semitropical rains frequently furnish.

The sewage also has to be pumped, and because it would tend rapidly to create a nuisance, if discharged into our shallow tidal lakes, it is discharged against a greater lift, through cast iron force mains, into the Mississippi River, entering the river well under the low water surface, in a direct downstream current at three points along the lower city river

front. Sewage so discharged is at once disposed in the vast volume of muddy river water, and does not even appear at the surface.

In order to obtain effective drainage with rainfalls sometimes as much as $3\frac{1}{2}$ inches in an hour, 7 inches in five hours, or 9 inches in twelve hours, over an area of 30,000 acres, there are six major drainage pumping stations having capacities ranging from 1,700 cubic feet to 3,000 cubic feet a second, with individual pumping units up to 700 cubic feet a second for storm duty, and down to 40 cubic feet a second or less for constant duty pumping. The aggregate capacity of these storm drainage pumps is about 7,000,000,000 gallons a day. Some of the drainage is lifted four times, and most of it at least twice, before it is finally delivered into the tide level leveed outfall canals, the aggregate lift probably averaging about 18 feet. These drainage pumps are operated electrically from two power stations, owned by the sewerage and water board, which have a maximum capacity of about 12,000 horse power. These drainage pumps constitute the greatest and most economical aggregation of low lift pumping machinery that exists. Seven billion gallons of water is equal to a lake having an area of a square mile over a depth of 33 feet, or to a column of water 10 feet square passing a given point at a rate of more than $1\frac{1}{4}$ miles every minute. Most of the drainage pumps were designed especially by the mechanical engineer of the sewerage and water board to meet local requirements, and were built in accordance with these

designs, without any guarantee that they would even pump water at all. They are, in effect, siphons over a division wall between the low level drain from which they pump and the higher level drain into which they discharge. At the summit of these siphons, properly designed screw blades, operated by a motor through a horizontal shaft, impel the water forward after the pump has been primed by the exhaustion of the air from its case, accomplished by a vacuum pump.

THE CHARITY HOSPITAL

This arrangement results in accessibility of all parts for maintenance and repairs, in the avoidance of gates and check gates and of great depths of excavation and foundation costs, and the simplification of the starting of the various units as they are needed. The greatly increased economy and efficiency which this type of pump and this arrangement have now demonstrated are fully recognized.

The main drains of the drainage system are called locally "covered and lined canals." They are built of concrete, reinforced with steel, and are often 25 feet wide and from 9 to 10 feet deep, with V-shaped bottoms to facilitate the movement of small or dry weather flows. These and all other drains, as well as the sewers in New Orleans, operate purely by gravity with good falls or slopes to the pumping stations, each station, by its performance, creating artificially a low outlet where none could exist otherwise. There is no reservoir capacity other than the drains or sewers in either case; as the water reaches each pumping station it must be lifted.

On the sewerage system there are seven intermediate lift pumping stations which pump the sewage from the low level gravity sewer, leading to them, into the higher level gravity sewer, leading away from them, through lifts of from 8 to 15 feet; and there are three final discharge sewage pumping stations which discharge the sewage, under pressure, through cast iron pipe lines into the river. The pumps at the latter stations make lifts of from 40 to 80 feet, depending on the level of the water in the river, and the friction in the long pressure mains through which they discharge.

The seven intermediate lift sewage pumping stations are interesting, because they are operated without any screening of the sewage and without any attendants, the pumps being automatically started or stopped one at a time by float-operated switches actuated by the level of the sewage in the low level sewer. The pumps are located in dry wells, and set down deep enough to be self priming. One of the most difficult problems to be solved has been to design pumps that would operate satisfactorily under these conditions. People will throw rags and similar matter into the sewers, and rags so seriously obstruct the usual type of low lift pump that screening of the sewage alone will permit it to operate with reasonable efficiency; and screening calls for an attendant at each station all the time and for an objectionable screening

to flow back and forth and up and down through a distance of about a mile, and which require about an hour of travel. This results in a perfect mixture of chemical solutions with the water and in perfect and uniform chemical reactions without any such violent agitation as would tend to break up flakelike hydrates, which act to entangle and bring together the suspended matter which the water contains. Passing out of the mixing channels, the water goes through settling basins of about seven hours' capacity, where the subsidence of the suspended matter is rapidly effected.

The use of lime as applied in New Orleans is not only to assist in coagulation of the suspended matter in the water but also for the softening of the water, the dissolved carbonates of lime and magnesia in the effluent being reduced always to about 40 parts per million.

After the water passes the settling basins it goes directly to the filters, which are of the so-called mechanical type, but are open gravity sand filters. The water passing to the filters usually does not carry more than 30 parts per million of suspended matter, and this is so effectually coagulated that in rapid passage through very coarse sand every particle of suspended matter and practically all bacteria are removed, the resulting effluent being clear, relatively soft, and of excellent sanitary quality.

After filtration, on its way to the pumps, which deliver it into the city distribution system, the water is given a treatment, proportional to the flow of water, of chlorin, roughly, about $1\frac{1}{2}$ pounds per million gallons, for sterilization. This general process has been in use since 1909, and has given most excellent results in every way. The New Orleans plant is among the first

removal service. To avoid this, an entirely new type of centrifugal pump has been devised by the board's mechanical engineer, and installed at these stations. It is called a "trash pump," and is just that. These pumps at the New Orleans stations have 12-inch suction and discharge openings; and a 12-inch ball or a succession of 12-inch balls, or a few table cloths or napkins or old clothes or kitchen or toilet utensils, are all the same to these pumps; any trash that can get into them at all is bound to go through and has no effect to decrease their efficiency, which is high through a wide range of lifts.

The water supply of New Orleans is taken from the Mississippi River at the extreme upper end of the city. Mississippi River water is very muddy, averaging 650 parts per million of suspended matter, and rather hard, but not so bad as river waters generally are in number of bacteria, and especially in the number of *B. coli* indicative of pollution. The suspended matter in the river water, however, is mostly very finely divided clay, and is impossible to remove in any practicable time by plain subsidence.

TREATMENT OF WATER SUPPLY

The method of treatment at New Orleans is a continuous process: The raw water pumped from the river first passes through a grit chamber having a capacity of about one hour's supply; then it passes the chemical flow governing apparatus on its way to the mixing channels. This apparatus governs flows of solution of ferrous sulphate and of milk of lime which enter the main flow of water proportional to the flow of water. The lime is added at the point where the main flow of water enters the mixing channels, and the iron at the point about half way through the mixing channels. These channels are a series of passage ways which cause the water

THE PARKS OF NEW ORLEANS

2. Tropical Road, City Park.
3. West End Park, Lake Pontchartrain.

of the larger plants of this character, many of which are now in operation, and it has fully met the hopes and expectations of those who planned it.

In this system the cleaning of the filters is effected by sending filtered water backward through them at a very rapid rate for a short period. The "wash water" used for this purpose, of course, has to be wasted. Usually an appreciable percentage of the water filtered has to be utilized for filter washing. The New Orleans plant has the exceptionally low record of only 0.5 per cent. of the water filtered required for filter washing.

The soil of New Orleans is all alluvial, composed of varying proportions of very fine sand and of soft or softer clay, with peaty strata frequently, and often with cypress stumps or logs in very large number. The construction and main-

tenance of sewers, drains, water mains and other underground structures, and of reservoirs, etc., under these soil conditions has itself been an interesting and often a difficult and expensive problem. Work under these conditions, particularly where resources were limited and the dollar had to be extended to cover the greatest possible results in service, is certain to carry some surprises and some grief.

The New Orleans water, sewerage and drainage systems, however, have from the day of their first tryout gone into service and given service continuously ever since. Clear, safe water under adequate pressure and up to the United States Public Health Service standard has been constantly available since Feb. 7, 1909, when the filters and purification systems were first tried for their intended use. Sewage removal from all premises from the first day of their connection with the sewers has been effective and continuous, and the storm water drainage system has never failed to go to the limit of its capacity in the prompt removal of accumulating storm flows.

The water consumers of New Orleans are all metered; but the water rates are so low that the small consumer, especially, is not sufficiently interested to prevent a good deal of needless waste, and the consumption per capita supplied has been gradually increasing for the last four or five years, having increased nearly 25 per cent. in that period.

EFFECT OF WATER SUPPLY ON MORTALITY RATE

The accompanying tabulation of local mortality statistics illustrates, probably better than anything else, the vital bearing of sanitary conditions on one question in which every one has a real interest, namely, the duration of the average human life in the community in which he lives, because it has a very close connection with the health, comfort, prosperity and probable length of life of his loved ones and of himself.

If the death rate of New Orleans, as proved in this tabulation, before either of these systems was put into effect, that is, from 1890 to 1899, was such that the average expectancy of life was only 36.7 years, and if, as one after another these systems have been put into use and brought gradually to their maximum usefulness, the general death rate has gradually reduced until in 1919 it was at that point which indicates an average expectancy of life of fifty-five years, it would seem that the foundation work without which this increase in life expectancy of eighteen years could not have possibly been obtained, is, from this point of view alone, worth its cost.

Calculated exactly in dollars, the average per capita cost paid either in taxes or water rates by the people of New Orleans for the sewerage, water and drainage systems for construction, maintenance and operation and interest to attain this result from 1895 to date has been about \$87, gradually increasing as more and more benefits to more and more people were provided, from about \$1 per annum per capita from 1895 to 1900, before any benefits were felt, to \$6.60 per capita per annum in 1919, when very nearly the whole population received the full benefit of all three systems.

According to the 1918 financial statistics of cities, compiled by the United States Census, cities of 300,000 or over of population collected from their people on an average, 79 per cent. per capita more for their water supply than New Orleans collected, and in net revenue available for expenditure for every form of municipal service, 73 per cent. more than New Orleans. In both of these items, New Orleans shows the

lowest per capita collections of any of the twenty-two cities of 300,000 population or over.

MORTALITY STATISTICS

Date	Death Rate Per 100,000 from		Per 1,000 All Causes	Corresponding Life Expectancy Based on Total Death Rate Years	Comment
	Malaria	Typhoid*			
1880-1889	156	21	28.6	35.0	No adequate drainage and vaults; cesspools, foul gutters and rain water cisterns were everywhere with mosquitoes abundant †
1890-1899	104	39	27.2	36.7	
1900-1909	26	38	22.6	44.2	From 1900, drainage improvements were effective and increasing
1910-1919	7	21	20.4	49.0	Connections to sewers started in 1906 and to water mains in 1909, with gradual increasing utilization of both systems
1919	4	13	18.2‡	55.0	93% of population served by sewers; 96% by water

* Typhoid in New Orleans appears never to have been water borne, but to have been due to importation and local communication through milk, food, etc., by insects or by carriers. An abundant supply of perfectly safe water with adequate facilities for cleansing and prompt removal of all infected material through the sewerage system are the only helpful influences which the sewerage or water system can contribute toward its further reduction. The increased typhoid from 1890 to 1909 was probably due to the gradual introduction of toilets draining to cesspools, which too frequently overflowed (illegally) into the old open street gutters to get rid of their surplus water.

† Since 1900, the decrease in the number of mosquitoes of all kinds has been marked and progressive as drainage has been extended and improved, as the sewers have acted to subdrain the soil, as rain water cisterns have gradually disappeared, and as open gutters have given place to pipe drains or been provided with outlet conditions which prevented standing water in them. Also, as a matter of great importance following the subsurface drainage, burials above ground are no longer necessary, and cellars can be dug and used in any part of the city, thus affording an enormous increase in property values through the increased space available.

‡ Of this 18.2, 1.75 was due to influenza exclusive of 100 additional due to pneumonia. It would appear, therefore, as though an average death rate of 18 per thousand is not too good to hope for in the early future, notwithstanding the too high mortality among the colored (one third of the population), and the large number of deaths in city hospitals of nonresident patients brought in from Louisiana and surrounding states. Better education and housing facilities for the colored and less well to do population generally should bring still further improvement.

§ Of this 18.2, 1.75 was due to influenza exclusive of 100 additional due to pneumonia. It would appear, therefore, as though an average death rate of 18 per thousand is not too good to hope for in the early future, notwithstanding the too high mortality among the colored (one third of the population), and the large number of deaths in city hospitals of nonresident patients brought in from Louisiana and surrounding states. VACATIONING AROUND NEW ORLEANS

On the shores of Lake Pontchartrain, easily accessible by electric car or automobile is West End, one of the delightful breathing spots which surround New Orleans. There is a great seawall, in back of which is a wide area of beautiful driveways, gardens and trees. Here, and also at Spanish Fort or Milneburg are excellent facilities for lounging and resting, for fishing, or other vacation delights.

Convenient also to the city are Waveland, Pass Christian, Gulfport, Long Beach and Ocean Springs—famous resorts whose names are so familiar as to conjure up at once thoughts of golf, tennis, bathing, fishing, boating, or the other pastimes of the convention vacationist.

New Orleans promises true Southern hospitality. Its facilities for instruction, for entertainment and for pleasure will be fully at the service of its guests.

TRANSPORTATION

Winter Tourist Rates Announced

The managers of the several passenger bureaus and traffic committees have advised that winter tourist fares will be in effect to New Orleans for the coming annual session of the American Medical Association. Tickets will be on sale at principal railroad centers up to April 30. They will be limited for return passage to May 30.

Round trip fares from Chicago, it is announced, will be \$51.03; from St. Louis, \$38.02; from Indianapolis, \$46.70; from Omaha (via Chicago), \$78.15, and (via St. Louis) \$58.50; from Louisville, Ky., \$40.35; from Cleveland, \$58.34; from Boston, \$83.94; from New York, \$73.14; from Washington, D. C., \$60.93; from Philadelphia, \$68.28; from Denver (via Chicago), \$87.70, (via St. Louis) \$74.05; from Portland, Ore., \$147.73; from San Francisco or Los Angeles, \$113.85. To all the foregoing fares, a war tax of 8 per cent. should be added. At a slight additional cost and in some instances for the same fare, diverse routes may be had from points from which tourists fares are quoted. The rates named above apply when going and returning by the same route.

These winter tourist rates are not in effect from points in certain Southern states. The following one way fares are announced: from El Paso, Texas, \$38.70; from Dallas, Texas, \$18.28; from Jackson, Tenn., \$13.27; from Augusta, Ga., \$19.17; from Birmingham, Ala., \$10.65. To these rates 8 per cent. war tax must also be added.

Consult Local Ticket Agent

Those who are planning to go to New Orleans should consult the local ticket agent in their home town in order to obtain full information regarding rates, time limits, extensions and stop-over privileges which may be had on the railroad tickets to New Orleans. It is advisable to make these inquiries at an early date as local ticket agents may have to ask for information desired, and except in the larger cities, it may be necessary to obtain a special form of ticket from some central ticket office. Neglecting to arrange for railroad tickets until just before the time for leaving home may make it necessary for the ticket agent to sell a full fare one way ticket since he may have neither the proper form nor the authority to sell these winter tourist excursion tickets. The importance of an early inquiry is emphasized.

Special Trains

Special trains from Chicago to New Orleans, to be known as the "American Medical Special" and the "Chicago Special," will be arranged to run over the Illinois Central Railroad Lines as sections of the regular trains—or special cars will be carried on these regular trains—as Pullman reservations warrant. There are three trains leaving Chicago daily for

New Orleans: at 8:45 a. m., at 12:30 p. m. and 6:15 p. m. These trains are scheduled to arrive in New Orleans, respectively, at 11 a. m., 11:15 a. m. and at 8:45 p. m. Pullman reservations can be made either through the railroad ticket office at your own home, or by addressing Mr. J. W. Stevenson, district passenger agent, Merchants Loan and Trust Building, 112 West Adams Street, Chicago. Members of the House of Delegates should plan to leave Chicago not later than 6:15 p. m., Saturday, April 24. Those who are interested chiefly in the meetings of the Scientific Assembly will reach New Orleans in ample time for the general opening meeting, which will be held on Tuesday evening, if they leave Chicago as late as 12:30 p. m., Monday, April 26.

Sleeping Cars to Be Parked

The R. & S. Tourist Company, 107 West Jackson Boulevard, Chicago, is arranging to run a special train leaving Chicago on Sunday, April 25, about noon, via the Illinois Central Railroad, and to arrive in New Orleans during the afternoon of Monday following. This train will return, leaving New Orleans about 7 p. m., April 30, and arriving in Chicago, Saturday evening, May 1. Arrangements will be made so that the cars will be parked in New Orleans at a convenient location. This will permit of the cars being used as sleeping quarters during the time of the annual session. The cost covering railroad fare, Pullman accommodations going and coming and during the days spent in New Orleans, is announced to be \$102.75 and up in accordance with the Pullman accommodations reserved. Particulars and definite information can be obtained by addressing the company. This use of Pullman sleeping cars by organized parties is commonly followed at the time of the Mardi Gras and other large gatherings at New Orleans.

Going to New Orleans by Boat

The *Comas*, one of the steamships of the Morgan Line, is announced to sail from New York, April 21, for New Orleans, and from New Orleans on the return trip on the morning of May 1. This boat can carry seventy-one first class passengers. In addition, there is space for thirty second class passengers. Particulars regarding time of sailing, rate of passage and other matters can be obtained by addressing Mr. A. J. Poston, general agent, Southern Pacific Lines, 165 Broadway, New York.

Dr. Ira J. Haynes, P. O. Box 24, Richmond, Va., who has undertaken to arrange for a party to go by boat from Boston to New Orleans, advises that he is experiencing some difficulty in securing a first class ship for the trip. However, he has in prospect a 3,000 ton vessel and states that if practical rates can be secured, the prospects are that this boat will be filled to capacity when it leaves Norfolk.

REGISTRATION

The Importance of Registering Early—A Few Suggestions Which Will Facilitate Registration

The Bureau of Registration will be located in the Josephine Hutchinson Memorial Building, Canal Street, between Villere and Robertson streets. A committee of local physicians will assist those desiring to register. A branch post-office will be opened, and a bureau of information established in connection with the Registration Bureau. Here may be secured copies of the *Daily Bulletin*, which announces the names of visitors and other important convention material.

Every one who registers will be required to fill out completely the spaces on both parts of the double registration cards, which will be found on the tables in front of the Registration Bureau. These entries should be written very plainly, or printed, as the cards are given to the printer to use as "copy" for the *Daily Bulletin*.

1. Fellows who have their pocket cards with them can be registered with little or no delay. They should present the

filled out registration card, together with their pocket card, at one of the windows marked "Registration by Pocket Card." There the clerk will compare the two cards, stamp the pocket card and return it, and supply the Fellow with a copy of the official program and other printed matter of interest to those attending the annual session.

2. Those Fellows who have forgotten their pocket cards should present the filled in registration card at the window marked "Paid—No Card." The work of registration at this window will be conducted as rapidly as possible; but the necessity of finding the Fellow's name on the Fellowship roster may occupy a considerable time and will occasion inconvenience to those who neglect to bring their pocket cards with them.

3. The Fellow whose 1920 dues are unpaid should present his filled in registration card with the amount of his Fel-

lowship dues (\$5) at one of the windows and marked "Cash." Here, too, there will be occasioned some delay; but the work of registering will be conducted as promptly as possible.

4. It will assist in registering if those who desire to qualify as Fellows will file their applications and qualify as Fellows by writing directly to the American Medical Association, 535 North Dearborn Street, Chicago, so that their Fellowship may be entered not later than April 19. Any applications received later than April 19 will be given prompt attention, but the Fellowship pocket card may not reach the applicant in time so that he can use it in registering at the New Orleans Session, and he may be required to make a second payment of his Fellowship dues, which must be held until the records at the headquarters can be consulted after the close of the session, when any excess payment will be satisfactorily adjusted.

If, however, a member of the Association neglects to qualify as a Fellow before reaching New Orleans he may be entered as a Fellow at the meeting by the following procedure: He should present a filled in registration card, together with a formal application for Fellowship at the window marked "New Fellows." These applications for Fellowship can be obtained at Window No. 1 of the Registration Bureau or

from the members of the Committee on Registration. In order to qualify as a Fellow, the applicant must be officially reported as a member of the constituent association of the state in which he resides, and in addition to filing this formal application, he must pay his annual Fellowship dues for the current year; if already a subscriber to *THE JOURNAL*, with his subscription paid for a term to or beyond Jan. 1, 1921, no additional payment is necessary. If subscription is not paid in full for the current year, the payment of a sum to extend it to Jan. 1, 1921, is required.

Those who will apply for Fellowship at New Orleans should provide themselves, before leaving their homes, with certificates of membership signed by the secretary of their state association certifying to their being members in good standing for 1920 in the state and county branches of the organization; a membership card for 1920 issued by the constituent association will be accepted. Failure to provide themselves with such a certificate will necessarily subject them to considerable delay in registering, if it does not preclude their being able to qualify for Fellowship at the time of the meeting. It will not only subject them to great annoyance, but will also be an imposition on other physicians desiring to register and attend the meetings of this session.

THE JOSEPHINE HUTCHINSON MEMORIAL BUILDING

Scientific Exhibit, Registration, Commercial Exhibit, Information Bureau and Postoffice in This Building
Meeting Place of the Sections on Stomatology, Dermatology, and Urology

HOTEL ACCOMMODATIONS

Dr. J. J. Wymer, 921 Canal St., New Orleans, Chairman of the Committee on Hotels, will handle promptly requests for reservations for lodgings. In writing to Dr. Wymer, he should be advised of the number who will be in the party, the time of arrival in New Orleans and how long the party will stay in that city, as well as the character of the lodgings desired. In addition to the available accommodations in the hotels, this committee has arranged to make available a large number of rooms in well appointed boarding houses as well as in private homes. Those who plan to attend the annual session are urged to make their reservations as promptly as possible. It is desirable that when New Orleans is reached, the party shall know exactly where they expect to be lodged. There will be an information bureau at each railroad station during the days of the session. These will be in charge of medical students from Tulane who will assist incoming Fellows to secure lodgings or direct them to the places where these are reserved.

POSTOFFICE

An Association Postoffice will be maintained in connection with the Registration Bureau in the Josephine Hutchinson Memorial Building. Guests are requested to order mail addressed to them "Care American Medical Association, Josephine Hutchinson Memorial Building, New Orleans, La.," or to their hotels, as preferred.

CLINICS IN NEW ORLEANS

The Local Committee on Arrangements reports that the medical profession of New Orleans is arranging a series of clinics to be conducted by members of the local profession on April 22 to 24, inclusive, and also on April 26 and 27 and May 1. These clinics will be open to Fellows of the Scientific Assembly from other states as well as to the members of the Louisiana State Medical Society, whose annual session is called for the week before the Association's session.

MEETING PLACES AND SECTION HEADQUARTERS

The following have been designated as general and section hotel headquarters, and as meeting places* for the New Orleans session—April 26 to 30:

HOUSE OF DELEGATES: *Orleans Parish Medical Society Building.*

PRACTICE OF MEDICINE: St. Charles. *Elks Hall.*

SURGERY, GENERAL AND ABDOMINAL: Grunewald. *Grunewald, Convention Hall.*

OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY: Grunewald. *Grunewald, Convention Hall.*

OPHTHALMOLOGY: Monteleone. *Moose Hall.*

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY: Monteleone. *Moose Hall.*

DISEASES OF CHILDREN: St. Charles. *Elks Hall.*

PHARMACOLOGY AND THERAPEUTICS: Planters. *Grunewald, Green Room.*

PATHOLOGY AND PHYSIOLOGY: Grunewald. *Grunewald, Green Room.*

STOMATOLOGY: Lafayette. *Hutchinson Memorial Building, Faculty Room.*

NERVOUS AND MENTAL DISEASES: Lafayette. *Charity Hospital Amphitheater.*

DERMATOLOGY: De Soto. *Hutchinson Memorial Building, Lower Amphitheater.*

PREVENTIVE MEDICINE AND PUBLIC HEALTH: De Soto. *Loyola Hall.*

UROLOGY: St. Charles. *Hutchinson Memorial Building, Lower Amphitheater.*

ORTHOPEDIC SURGERY: Grunewald. *Charity Hospital Amphitheater.*

GASTRO-ENTEROLOGY AND PROCTOLOGY: Lafayette. *Loyola Hall.*

GENERAL HEADQUARTERS: Grunewald.

SCIENTIFIC EXHIBIT, REGISTRATION BUREAU, COMMERCIAL EXHIBIT, INFORMATION BUREAU AND BRANCH POSTOFFICE: Hutchinson Memorial Building.

* Meeting places in italics.

17. The Shrine Mosque.
18. The Athenaeum.

NONAFFILIATED ORGANIZATIONS

The following organizations have announced that they will hold meetings in New Orleans during the days immediately preceding those on which the Scientific Assembly of the American Medical Association will meet: Air Service Medical Association of the United States; American Radium Society; Association for Study of Internal Secretions; Association of American Teachers, Diseases of Children; Association of Military Surgeons of the United States; Louisiana State Medical Society; Medical Veterans of the World War, and the Radiological Society.

GUESTS FROM FOREIGN COUNTRIES

Among others, Sir Humphrey Davy Rolleston and Col. H. J. Waring of London; Drs. Norman Walker and A. H. Freeland Barbour of Edinburgh; Prof. Victor Morax, Paris; Prof. J. C. Connel, Kingston, and Alexander Primrose, Toronto, are expected to be in attendance at the New Orleans Session. It is anticipated there will also be a number of physicians from Mexico and South America. Accredited physicians from foreign countries will be registered as "invited guests" and may participate in the functions of the annual session.

ENTERTAINMENT

(NOTE.—The official badge will be required for admission to entertainments and other places to which entrance is granted to those in attendance on the annual session.)

The President's Ball

While there will be many and varied entertainments provided for amusement of the Fellows, and their wives, daughters and friends, an original and characteristic program has been perfected for an event to be known as the President's Ball. This will be a carnival ball with a number of tableaux representing medical subjects or interest, humor, and perhaps a little satire. The indications are that this ball will be fully as beautiful as any heretofore given, even in the halcyon days of prewar carnival revelry. It will be carried out in exact accordance with the historical procedure for such affairs. The scenery and settings will be specially painted and prepared to suit the theme. There will be the king with his royal court who will preside over the cast, limited to 150 of the most worthy subjects, all of them gorgeously costumed as will be befitting the characters they portray and the illustrious onlookers before whom they will have the honor of appearing. The king will have his queen and the dukes of his court, their maids, and after the completion of the tableaux they with the maskers will dance in a series until every one of the fair guests has been called out.

After this has been accomplished the maskers will gradually disappear, black coats will come on, and the dancing will continue. Dr. Amedee Granger, Chairman of the Committee on Entertainment, 921 Canal Street, requests that there be submitted to him the names of ladies who will be interested in taking part in the "Carnival Ball," in order that they may be informed concerning the unique features of this event and that they may be assigned "call out seats."

This form of entertainment is novel so far as the American Medical Association is concerned. It is essentially characteristic of the happiest life in the Crescent City. The ball will be given on the evening of April 28.

Fete Champetre

On April 29, a Fete Champetre will be given at the City Park and the Committee on Entertainment is doing all in its power to make this fete both entertaining and instructive.

Entertainment for Visiting Ladies

Trips are being arranged through the historical and beautiful sections of New Orleans for the visiting ladies. These will be personally conducted by members of the Louisiana Historical Society in the forenoon. In the afternoons there will be receptions and automobile rides.

AMERICAN MEDICAL GOLF TOURNAMENT

The Sixth Tournament of the American Medical Golf Association will be held at the New Orleans County Club, April 26, under the auspices of the Local Committee: Clyde Lynch, chairman; Larry DeBuys; John Elliott, Jr., secretary, 803 Audubon Building, New Orleans.

The events will take place both morning and afternoon. They consist of the Association championship, thirty-six holes gross, "Frisco" trophy; Association handicap, thirty-six holes, Detroit trophy, and choice score handicap, thirty-six holes, New Orleans trophy. By order of the 1919 meeting, the members of the Handicap Committee are: Charlton

Wallace, Eastern District, 11 East Forty-Eighth Street, New York; J. J. Coons, Central District, 122 East Broad Street, Columbus, Ohio, and Fred Bailey, Western District, 816 University Club Building, St. Louis.

Any Fellow of the American Medical Association in good standing, who has a degree of M.D. becomes automatically a member of the American Medical Golf Association, on acceptance of the by-laws and payment of the enrolment fee. The enrolment fee consists of \$2, payment of which confers life membership. A playing fee of \$1 is charged on entrance in the tournament.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit will be located on the third floor of the Josephine Hutchinson Memorial Building of the Medical Department of Tulane University, on the north side of Canal Street, between Villere and Robertson Streets, about three blocks from the Grunewald Hotel. The exhibitors who have so far made application for space are as follows:

MEDICAL DEPARTMENT, U. S. ARMY, Washington, D. C.: Exhibit on Scientific War Material.

LOUISIANA STATE BOARD OF HEALTH, New Orleans: Educational Exhibit.

AMERICAN MEDICAL ASSOCIATION:

Council on Pharmacy and Chemistry.

Propaganda Department.

Chemical Laboratory.

Council on Medical Education.

Council on Health and Public Instruction.

Exhibits showing the activities of the Association.

PRUDENTIAL LIFE INSURANCE COMPANY, New York: Exhibit on Graphic Charts, Showing Statistics of Leprosy, and the Sanitary Progress of New Orleans.

AMERICAN SOCIETY FOR THE CONTROL OF CANCER, New York: Exhibit Showing the Activities of the Organization.

ASSOCIATION FOR THE PREVENTION AND RELIEF OF HEART DISEASE, New York: Exhibit of Charts and Folders Explaining Development of Work.

MAYO CLINIC, Rochester, Minn.: Exhibit of Charts and Photographs.

DR. MARTIN H. FISCHER, Cincinnati General Hospital, Cincinnati: Exhibit on Colloid Chemistry in the Analysis of

Various Problems in Physiology, Pathology and Pharmacology.

DR. VICTOR D. LESPINASSE, Chicago: Exhibit on Spermatogenesis and Sterility.

DR. ANGELO L. SORESI, New York: Scientific Exhibit—Specimens—Illustrations—Instruments.

DR. WILLIAM H. MERCUR, Pittsburgh: Exhibit on the Method of Classification and Indexing of Case Records and Reprints.

DR. ALFRED A. STRAUSS, Chicago. Exhibit on Stomach and Intestinal Surgery—Sterility—Muscle and Tendon Transplantation.

DR. CHARLES WINFIELD PERKINS, New York: Exhibit on Gunshot Injuries of the Long Bones, Showing Osteogenesis.

DR. JAMES T. CASE, Battle Creek Sanitarium, Battle Creek, Mich.: Exhibit on Diet and Nutrition.

DR. HENRY A. COTTON, New Jersey State Hospital, Trenton, N. J.: Exhibit on Medical and Surgical Work of the Institution.

In addition, scientific material presented by New Orleans institutions and members of the local profession will be shown in Professor Bass' private laboratory.

The amphitheater on the third floor will be used for moving pictures, lantern slides and roentgen-ray exhibits during the time of the meeting. A detailed program of the moving picture exhibit will be announced later, and a final program and complete list of exhibitors will appear in the official program.

PRELIMINARY PROGRAM OF THE SCIENTIFIC ASSEMBLY

PROGRAM OF THE OPENING MEETING

SHRINERS' TEMPLE, ST. CHARLES AVENUE AND CLIO STREET
Tuesday, April 27—8:30 p. m.

Music.

Call to Order by the President, ALEXANDER LAMBERT, New York.

Invocation. Most Reverend J. W. SHAW, Archbishop of New Orleans.

Announcements, ALBERT E. FOSSIER, Chairman of the Local Committee of Arrangements.

Address of Welcome. HON. MARTIN BEHRMAN, Mayor, City of New Orleans.

Address of Welcome. President, Louisiana State Medical Society.

Address. HON. JOHN M. PARKER, Governor-Elect of Louisiana.

Music.

Introduction and Installation of President-Elect WILLIAM C. BRAISTED, U. S. Navy.

Address. WILLIAM C. BRAISTED.

Music.

THE PROGRAMS OF THE SECTIONS

Outline of the Scientific Proceedings—The Preliminary Program and the Official Program

The following papers are announced to be read before the various sections. The order here is not necessarily the order which will be followed in the Official Program, nor is the list complete. The Official Program will be a pamphlet similar to those issued in previous years, and will contain the final program of each section with abstracts of the papers, as well as lists of committees, programs of the General Meeting, lists of entertainments, map of New Orleans and other information. To prevent misunderstandings and to protect the interest of advertisers, it is here announced that this Official Program will contain no advertisements. It is copyrighted by the American Medical Association and will not be distributed before the session. A copy will be given to each Fellow on registration.

SECTION ON PRACTICE OF MEDICINE

MEETS IN ELKS' HALL

OFFICERS OF SECTION

Chairman—JAMES S. MCLESTER, Birmingham, Ala.

Vice Chairman—JOSEPH H. PRATT, Boston.

Secretary—G. CANBY ROBINSON, St. Louis.

Executive Committee—HENRY A. CHRISTIAN, Boston; LAWRENCE LITCHFIELD, Pittsburgh; WALTER L. BIERRING, Des Moines, Iowa.

(Stenographer—Dr. G. G. TAYLOR, Chicago)

Wednesday, April 28—2 p. m.

- Chairman's Address.
JAMES S. MCLESTER, Birmingham, Ala.
- The Clinical Interpretation of Basal Metabolic Rate Estimations.
HENRY S. PLUMMER, Rochester, Minn.
- The Nature of Fever.
WILLIAM D. SANSUM, Chicago.
- Types and Treatment of Pellagra.
STEWART R. ROBERTS, Atlanta, Ga.
- The End-Results of Focal Infections.
BRYCE W. FONTAINE, Memphis, Tenn.
- Abscess of the Lung.
U. J. W. PETERS, Birmingham, Ala.
- The Clinical Diagnosis of Obstruction of the Hepatic Veins.
CHARLES F. HOOVER, Cleveland.
- Phlebectasis of the Diaphragmatic Area and of the Lower Thoracic and Upper Abdominal Regions.
WILLIAM GERRY MORGAN, Washington, D. C.

Thursday, April 29—2 p. m.

- An Address.
SIR HUMPHREY DAVY ROLLESTON, London.
- Oxycephaly: Its Occurrence in Negroes.
GEORGE DOCK, St. Louis.
- Clinical Experience with a Standardized Dried Aqueous Extract of Digitalis.
JOSEPH H. PRATT, Boston.
- A Study of the Bile Pigments in Pernicious Anemia.
JOHN P. SCHNEIDER, Minneapolis.

- Spondylitis and Abdominal Pain.
DOUGLAS VANDERHOOF, Richmond, Va.

- The Influence of Quantitative Methods in the Advance of Clinical Medicine.
EUGENE S. KILGORE, San Francisco.

- Frozen Sections from Two Cases of Aneurysm of the Thoracic Aorta.
GEORGE W. NORRIS and GEORGE FETTEROLF, Philadelphia.

Friday, April 30—2 p. m.

Election of Officers

- Hints for the Diagnosis of Disease of the Gallbladder.
LEWELLYS F. BARKER, Baltimore.

- Gout: A Clinical Study of 116 Cases.
CHARLES SPENCER WILLIAMSON, Chicago.

- Renal Glycosuria.
JAMES E. PAULLIN, Atlanta, Ga.

- The Treatment of Diabetes Complicated by Pulmonary Tuberculosis.
NELSON W. JANNEY, Santa Barbara, Calif.

- Arterial Hypertension Associated with Endocrine Dyscrasia.
WILLIAM ENGELBACH, St. Louis.

- Syphilis of the Kidney.
LOYD THOMPSON, Hot Springs, Ark.

- Angina Abdominalis and Other Abdominal Manifestations of Arteriosclerosis.
ALFRED STENGEL, Philadelphia.

- The Effect of Tonsillectomy on the Recurrence of Acute Rheumatic Fever and Chorea in Children.
WILLIAM P. ST. LAWRENCE, New York.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

MEETS IN GRUNEWALD, CONVENTION HALL

OFFICERS OF SECTION

Chairman—DEAN D. LEWIS, Chicago.

Vice Chairman—MALVERN B. CLOPTON, St. Louis.

Secretary—GEORGE P. MULLER, Philadelphia.

Executive Committee—WILLIAM D. HAGGARD, Nashville, Tenn.; E. STARR JUDD, Rochester, Minn.; JOHN T. BOTTOMLEY, Boston.

(Stenographer—Miss LIDIE C. ALEXANDER, Philadelphia)

Wednesday, April 28—9 a. m.

- One Hundred Goiter Operations: Mistakes in Retrospect.
JAMES T. MASON, Seattle.
- Diagnosis and Management of Intrathoracic Thyroid Growths (Lantern Demonstration).
FRANK H. LAHEY, Boston.
- Advantages of Local Anesthesia in Thyroid Operations (Lantern Demonstration).
JOSEPH R. EASTMAN, Indianapolis.
- Technic of Thyroidectomy (Lantern Demonstration).
WILLARD BARTLETT, St. Louis.
Discussion of papers 1, 2, 3 and 4 to be opened by HENRY S. PLUMMER, Rochester, Minn.; WILLIAM D. HAGGARD, Nashville, Tenn.; EMIL GOETSCH, Brooklyn, and EDWARD G. JONES, Atlanta, Ga.
- Chronic Cystic Mastitis (Lantern Demonstration).
JOSEPH C. BLOODGOOD, Baltimore.
Discussion to be opened by WILLIAM C. MACCARTY, Rochester, Minn.
- Brain Abscess.
ALFRED W. ADSON, Rochester, Minn.
Discussion to be opened by HARVEY CUSHING, Boston, and ARTHUR C. STRACHAUER, Minneapolis.
- Hemangioma and Lymphangioma: Their Response to the Injection of Boiling Water (Lantern Demonstration).
FRANCIS LE S. REDER, St. Louis.
Discussion to be opened by JOHN A. WYETH, New York; RUDOLPH MATAS, New Orleans, and CURTIS F. BURNAM, Baltimore.

Thursday, April 29—9 a. m.

- Chairman's Address.
DEAN D. LEWIS, Chicago.
- Squamous-Cell Carcinoma of the Kidney.
ALEXANDER PRIMROSE, Toronto.
Discussion to be opened by ARTHUR D. BEVAN, Chicago.
- Congenital Hypertrophic Pyloric Stenosis in Infants: Review of 175 Cases in Which the Fredet-Rammstedt Operation was Performed.
WILLIAM A. DOWNES, New York.
Discussion to be opened by DEAN D. LEWIS, Chicago.

11. Ulcer of the Jejunum Following Gastro-Enterostomy.
WALLACE I. TERRY, San Francisco.
Discussion to be opened by E. STARR JUDD, Rochester, Minn.
12. Surgery of Cancer of the Large Intestines.
ARTHUR D. BEVAN, Chicago.
13. Operation for Carcinoma of the Rectum.
GEORGE W. CRILE, Cleveland.
Discussion to be opened by DANIEL F. JONES, Boston.
14. Roentgenologic Experience with Pneumoperitoneum (Lantern Demonstration).
ARTHUR STEIN and WILLIAM H. STEWART, New York.
Discussion to be opened by WILLY MEYER, New York, and GEORGE E. PFAHLER, Philadelphia.
15. Ether Oil Colonic Anesthesia.
WALTER LATHROP, Hazleton, Pa.
Discussion to be opened by JAMES T. GWATHMEY, New York.

Friday, April 30—9 a. m.

Election of Officers

16. Report of Gunshot Wounds of the Chest.
ARTHUR M. SHIPLEY, Baltimore.
Discussion to be opened by JOHN L. YATES, Milwaukee, and JAMES T. GWATHMEY, New York.
17. Importance of the "Vital Capacity" in Thoracic Surgery (Lantern Demonstration).
EVARTS A. GRAHAM, St. Louis.
18. Prevention and Treatment of Pleurisy.
JOHN L. YATES, Milwaukee.
19. Observations on the Relative Value of the Various Operative Procedures Employed in Acute Empyema.
CARL EGGERS, New York.
Discussion to be opened by ALEXANDER LAMBERT, New York; MARTIN B. TINKER, Ithaca, N. Y.; ARVINE E. MOZINGO, Indianapolis, and JAMES F. MITCHELL, Washington, D. C.
20. Fracture of the Femur: A Plea for a Better American Standard.
KELLOGG SPEED, Chicago.
Discussion to be opened by JOHN B. WALKER, New York.
21. Mobilization of Injured, Infected or Fractured Joints.
CLARENCE A. MCWILLIAMS, New York.
22. The Use of Bone and Fascia Grafts in the Reconstruction of Bones and Joints (Lantern Demonstration).
ADDISON G. BRENNER, Charlotte, N. C.
23. Mechanic Stability of Fractures Following Operation (Motion Picture Demonstration).
PAUL B. MAGNUSON, Chicago.

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

MEETS IN GRUNEWALD, CONVENTION HALL

OFFICERS OF SECTION

Chairman—REUBEN PETERSON, Ann Arbor, Mich.
Vice Chairman—FRANCIS LE S. REDER, St. Louis.
Secretary—SIDNEY A. CHALFANT, Pittsburgh.
Executive Committee—HOWARD W. LONGYEAR, Detroit;
BROOKE M. ANSPACH, Philadelphia; THOMAS J. WATKINS, Chicago.
(Stenographer—Miss LIDIE C. ALEXANDER, Philadelphia)

Wednesday, April 28—2 p. m.

1. Chairman's Address: The Future of Obstetrics and Gynecology as a Specialty.
REUBEN PETERSON, Ann Arbor, Mich.
2. Chronic Leukorrhea: Its Pathology and Treatment (Lantern Demonstration).
ARTHUR H. CURTIS, Chicago.
3. Conservation of the Menstrual Function.
WILLIAM J. MAYO, Rochester, Minn.
Discussion to be opened by C. JEFF MILLER, New Orleans.
4. Relation of Hyperplasia of the Endometrium to So-Called Functional Uterine Hemorrhage (Lantern Demonstration).
EMIL NOVAK, Baltimore.
5. A Plea for Total Hysterectomy in the Operative Treatment of Fibroid Tumors of the Uterus in Parous Women.
JOHN OSBORN POLAK, Brooklyn.
Discussion to be opened by EDWARD E. MONTGOMERY, Philadelphia.
6. Hernia of the Ovary.
WILLIAM W. GRANT, Denver.

7. Results of the Exposure of Animal Ovaries to the Rays of Radium (Lantern Demonstration).
JOHN M. MAURY, Memphis, Tenn.
Discussion to be opened by FRANCIS CARTER WOOD, New York.

Thursday, April 29—2 p. m.

8. The Sectional Anatomy of Labor (Lantern Demonstration).
A. H. FREELAND BARBOUR, Edinburgh.
9. A Consideration of Stillbirths and Neonatal Deaths in Their Relation to Obstetric Practice (Lantern Demonstration).
FRED L. ADAIR, Minneapolis.
Discussion to be opened by EDGAR J. HUENEKENS, Minneapolis, and N. SPROAT HEANEY, Chicago.
10. Abnormal Lactation (Lantern Demonstration).
MATTHIAS J. SEIFERT, Chicago.
11. Intra-Uterine Insufflation of Oxygen (Artificial Pneumoperitoneum) for the Determination of Patency of the Fallopian Tubes in Cases of Sterility.
ISADOR C. RUBIN, New York.
Discussion to be opened by EDWARD REYNOLDS, Boston.
12. The Treatment of Obstinate Occipitoposterior Positions.
JOSEPH B. DELEE, Chicago.
Discussion to be opened by RALPH H. POMEROY, Brooklyn.
13. The Policy of Noninterference in the Treatment of Post-abortive and Puerperal Infections.
EDWARD L. KING, New Orleans.
14. The Management of Acute Appendicitis in the Later Weeks of Pregnancy. Report of Case Treated by Cesarean Section and Appendectomy.
JAMES M. MASON, Birmingham, Ala.
Discussion to be opened by NORBORNE PAGE COCKE, Birmingham, Ala.

Friday, April 30—2 p. m.

Election of Officers

15. Prolapse of the Urethra in the Female (Lantern Demonstration).
RICHARD R. SMITH, Grand Rapids, Mich.
Discussion to be opened by S. M. D. CLARK, New Orleans.
16. An Operation for Pruritus of the Vulva and Anus.
CARROLL W. ALLEN, New Orleans.
17. The So-Called Cases of Nephralgia.
DEWITT B. CASLER, Baltimore.
Discussion to be opened by JOHN T. GERAGHTY, Baltimore.
18. Primary Suture of the Renal Pelvis and Ureter After Removal of Stones.
LE GRAND GUERRY, Columbia, S. C.
Discussion to be opened by BENJAMIN A. THOMAS, Philadelphia.
19. Cysts of the Pancreas (Lantern Demonstration).
JOHN J. GILBRIDE, Philadelphia.
Discussion to be opened by ALBERT J. OCHSNER, Chicago.
20. An Improved Technic for Cholecystectomy Based on an Anatomic Study (Lantern Demonstration).
MOSES BEHREND, Philadelphia.
Discussion to be opened by JABEZ N. JACKSON, Kansas City, Mo., and ALFRED C. WOOD, Philadelphia.
21. Appendicitis Caused by Amebae Dysenteriae. Post-operative Perforation of an Amebic Ulcer of the Cecum (Lantern Demonstration).
EDGAR P. HOGAN, Birmingham, Ala.
Discussion to be opened by WILLIAM F. SHALLENBERGER, Atlanta, Ga.

SECTION ON OPHTHALMOLOGY

MEETS IN MOOSE HALL

OFFICERS OF SECTION

Chairman—ALLEN GREENWOOD, Boston.
Vice Chairman—NELSON M. BLACK, Milwaukee.
Secretary—GEORGE S. DERBY, Boston.
Executive Committee—WILLIAM ZENTMAYER, Philadelphia;
ALEXANDER DUANE, New York; CASSIUS D. WESCOTT, Chicago.
(Stenographer—Miss F. E. DILLAN, Indianapolis)

Wednesday, April 28—9 a. m.

1. Chairman's Address.
ALLEN GREENWOOD, Boston.
2. Optic Nerve Disturbances in Diseases of the Posterior Nasal Sinuses.
JAMES BORDLEY, JR., Baltimore.
Discussion to be opened by GEORGE E. DE SCHWEINITZ, Philadelphia.

3. Optic Neuritis Associated with Disease of the Nasal Sinuses. EDWARD C. ELLETT, Memphis, Tenn.
Discussion to be opened by LEE M. FRANCIS, Buffalo.
4. Ocular Symptoms in Ophthalmic Goiter.
JOHN H. CLATBORNE, New York.
Discussion to be opened by ALBERT E. BULSON, JR., Fort Wayne, Ind.
5. Mercurochrome-220. A Clinical Laboratory Report on Its Use in Ophthalmology.
WALTER B. LANCASTER, FRANCIS L. BURNETT and LOUIS H. GAUS, Boston.
Discussion to be opened by HUGH H. YOUNG, Baltimore.

Thursday, April 29—9 a. m.

DEMONSTRATION SESSION. EXHIBITION OF NEW INSTRUMENTS AND APPLIANCES

6. Address: Extraction of Cataract in Glaucoma.
VICTOR MORAX, Paris.
7. Thermophor Studies in Glaucoma.
WILLIAM E. SHAHAN and LAWRENCE POST, St. Louis.
Discussion to be opened by JOHN O. MCREYNOLDS, Dallas, Texas.
8. Diagnosis of Chronic Intra-Ocular Tuberculosis.
HARRY H. STARK, El Paso, Texas.
Discussion to be opened by WILLIAM C. FINNOFF, Denver.
9. Ethylhydrocuprein in Diseases of the Eye.
ARTHUR J. BEDELL, Albany, N. Y.
Discussion to be opened by HARRY S. GRADLE, Chicago.
10. Communicating Vessels Between Retina and Choroid in Certain Cases of Chorioretinitis, with Remarks on a Fold of the Inner Limiting Membrane.
MARCUS FEINGOLD, New Orleans.
Discussion to be opened by EDWARD JACKSON, Denver.

Friday, April 30—9 a. m.

Election of Officers

Reports of Committees

11. Effect of Cold on the Temperature in the Orbit.
LUCIEN HOWE, Buffalo.
Discussion to be opened by ERASTUS E. HOLT, Portland, Maine.
12. Early Diagnosis of Pituitary Tumor with Ocular Phenomena.
WILLIAM L. BENEDICT, Rochester, Minn.
Discussion to be opened by F. PHINIZY CALHOUN, Atlanta, Ga.
13. Four Cases of Sympathetic Ophthalmia with Reference to Treatment with Large Doses of Salicylate of Sodium.
HERBERT MOULTON, Fort Smith, Ark.
Discussion to be opened by JAMES M. PATTON, Omaha.
14. A New Operation for the Relief of Dacryocystitis Through the Nasal Route.
MEYER WIENER and WILLIAM E. SAUER, St. Louis.
Discussion to be opened by WILLIAM H. WILDER, Chicago.
15. Restoration of the Margin of the Eyelid by a Free Graft from the Lower Part of the Eyebrow.
JOHN M. WHEELER, New York.
Discussion to be opened by NELSON M. BLACK, Milwaukee.

SECTION ON LARYNGOLOGY, OTOLOGY AND RHINOLOGY

MEETS IN MOOSE HALL

OFFICERS OF SECTION

Chairman—JOSEPH C. BECK, Chicago.
Vice Chairman—GEORGE M. COATES, Philadelphia.
Secretary—WILLIAM B. CHAMBERLIN, Cleveland.
Executive Committee—FRANCIS P. EMERSON, Boston; GREENFIELD SLUDER, St. Louis; LEE WALLACE DEAN, Iowa City.
(Stenographer—Miss F. E. DILLAN, Indianapolis)

Wednesday, April 28—2 p. m.

1. Chairman's Address. JOSEPH C. BECK, Chicago.
2. Plastic Surgery: Its Relation to the Otolaryngologist (Lantern Demonstration).
FERRIS N. SMITH, Grand Rapids, Mich.
3. Plastic Surgery of the Face.
MILLARD F. ARBUCKLE, East St. Louis, Ill.
4. Mixed Tumors of the Throat, Mouth and Face.
GORDON B. NEW, Rochester, Minn.
Discussion to be opened by LEE WALLACE DEAN, Iowa City.
5. Thyroid Surgery, Especially as Related to Laryngology.
JOHN F. BARNHILL, Indianapolis.
Discussion to be opened by GEORGE W. CRILE, Cleveland.

6. The Use and Possible Abuse of Radium in the Treatment of Malignant Tumors of the Nose and Throat.
ROBERT SONNENSCHNEIN, Chicago.
Discussion to be opened by WILLIAM L. CLARK, Philadelphia, and DUNBAR ROY, Atlanta, Ga.
7. Misleading Symptoms and Roentgen-Ray Findings in Suspected Mastoid Abscess.
RICHMOND MCKINNEY, Memphis, Tenn.
Discussion to be opened by SAMUEL IGLAUER, Cincinnati.

Thursday, April 29—2 p. m.

8. Present Status of Neuro-Otology from the Borderline Standpoint.
JOSEPH D. HEITGER, Louisville, Ky.
Discussion to be opened by HAROLD I. LILLIE, Rochester, Minn.
9. Intracranial Lesions Involving the Auditory Vestibular Apparatus.
EUGENE R. CARPENTER, Dallas, Texas.
Discussion to be opened by HARVEY CUSHING, Boston.
10. Neurolabyrinthitis Syphilitica.
GEORGE W. MACKENZIE, Philadelphia.
Discussion to be opened by GEORGE M. COATES, Philadelphia.
11. Clinical Manifestations of Infection of the Lateral Sinus.
FRANCIS P. EMERSON, Boston.
Discussion to be opened by WILLIAM E. SAUER, St. Louis.
12. Arthritis Deformans of the Larynx.
HENRY L. LYNNAH, New York.
Discussion to be opened by EMIL MAYER, New York.
13. The Indifference of the Laryngologist Toward Tuberculous Laryngitis and the Tuberculosis Problem.
WILLIAM V. MULLIN, Colorado Springs, Colo.
Discussion to be opened by JOHN B. McMURRAY, Washington, Pa.
14. The Diagnosis and Prognosis of Loss of Vision from Accessory Sinus Disease.
LEON E. WHITE, Boston.
Discussion to be opened by HARRY H. STARK, El Paso, Texas, and HANAU W. LOEB, St. Louis.

Friday, April 30—2 p. m.

Election of Officers

EXHIBITION OF NEW INSTRUMENTS AND APPLIANCES

Report of Committees

- Special Report on Local Anesthesia by the Committee on Therapeutic Research.
EMIL MAYER, New York, Chairman; ROSS HALL SKILLERN, Philadelphia, and ROBERT SONNENSCHNEIN, Chicago.
Discussion to be opened by RUDOLPH MATAS and CARROLL W. ALLEN, New Orleans.
15. Harelip and Cleft Palate. OWEN SMITH, Portland, Me.
Discussion to be opened by THOMAS E. CARMODY, Denver.
 16. New Method of Closing an Enlarged Tooth Root Opening into the Maxillary Antrum.
CULLEN F. WELTY, San Francisco.
Discussion to be opened by JOSEPH A. STUCKY, Lexington, Ky.
 17. Relative Value of Transillumination and Roentgenography in the Diagnosis of Disease of the Maxillary and Frontal Sinuses; with Description of an Orbitopalatal Route of Transilluminating the Maxillary Sinus (Lantern Demonstration).
HENRY H. BRIGGS, Asheville, N. C.
Discussion to be opened by J. WILKINSON JERVEY, Greenville, S. C.
 18. Nerve Blocking for Nasal Surgery.
ROBERT G. REAVES, Greensboro, N. C.
Discussion to be opened by HENRY H. MARTIN, Savannah, Ga.

SECTION ON DISEASES OF CHILDREN

MEETS IN ELKS' HALL

OFFICERS OF SECTION

Chairman—FRITZ B. TALBOT, Boston.
Vice Chairman—JULIUS H. HESS, Chicago.
Secretary—E. C. FLEISCHNER, San Francisco.
Executive Committee—JULIUS P. SEDGWICK, Minneapolis; LAURENCE R. DEBUYS, New Orleans; FRANKLIN P. GENGENBACH, Denver.
(Stenographer—Dr. G. G. TAYLOR)

Wednesday, April 28—9 a. m.

1. Chairman's Address: The Future of Pediatrics.
FRITZ B. TALBOT, Boston.
2. The Treatment of Indigestion in Children.
JOHN LOVETT MORSE, Boston.

3. The Treatment of Indigestion in Children from Six to Twelve Years of Age.
HARRY M. McCLANAHAN, Omaha.
4. The Relation of Acquired Food Dislikes of Childhood to the Diseases of Middle Life.
C. HILTON RICE, JR., Montgomery, Ala.
5. A Few Pertinent Questions on Maternal Feeding.
WILLIAM A. MULHERIN, Augusta, Ga.
6. How Pediatric Teaching of Nutrition May Affect the Nation's Welfare.
HENRY DWIGHT CHAPIN, New York.
7. Vegetable Fats in Infant Feeding.
GEORGE DOW SCOTT, New York.

Thursday, April 29—9 a. m.

8. Observations on Tumors of the Kidney in Children.
WILLIAM E. CARTER and LANGLEY PORTER, San Francisco.
9. Chronic Nephritis in Children.
LEWIS WEBB HILL, Boston.
10. Local Anesthesia in Surgery in Infancy and Childhood.
ROBERT E. FARR, Minneapolis.
11. Infantile Spinal Progressive Muscular Atrophy (Werdnig-Hoffmann).
EDGAR J. HUENEKENS, Minneapolis.
12. Human Heart with only Two Chambers (Cor Biloculare).
HARRY H. DONNALLY, Washington, D. C.
13. Acrodynia.
WILLIAM WESTON, Columbia, S. C.

Friday, April 30—9 a. m.

Election of Officers

14. The Temporary Teeth: Disorders Due to Their Neglect.
J. ROSS SNYDER, Birmingham, Ala.
15. The Coagulation Time of Blood in the New-Born with Special Reference to Cerebral Hemorrhage.
FREDERICK C. RODDA, Minneapolis.
16. Studies of the Effect of Diphtheria Toxin on the Heart.
HUGH McCULLOCH, St. Louis.
17. The Antiscorbutic Value of Proprietary Baby Foods.
JOSIAH J. MOORE, Chicago.
18. Intramuscular Injections of Blood as an Aid to Nutrition.
THOMAS D. PARKE, Birmingham, Ala.
19. Intubation of the Larynx: Analysis of 440 Cases in Private Practice
HENRY J. CARTIN, Johnstown, Pa.

SECTION ON PHARMACOLOGY AND THERAPEUTICS

MEETS IN GRUNEWALD, GREEN ROOM

OFFICERS OF SECTION

Chairman—GEORGE W. MCCOY, Washington, D. C.
Vice Chairman—LEONARD G. ROWNTREE, Minneapolis.
Secretary—CARY EGGLESTON, New York.
Executive Committee—A. W. HEWLETT, San Francisco;
ARTHUR D. HIRSCHFELDER, Minneapolis; W. A. BASTEDO, New York.
(Stenographer—Miss MARGARET I. MALONEY, Chicago)

Wednesday, April 28—9 a. m.

1. Chairman's Address
GEORGE W. MCCOY, Washington, D. C.
2. The Actions of Some Homologues of Benzyl Alcohol.
ARTHUR D. HIRSCHFELDER, Minneapolis.
3. Some Observations on the Pharmacology of a Digitalis Body.
ROBERT A. HATCHER, New York.
4. Clinical Observations on the Absorption of Digitalis.
CARY EGGLESTON, New York.
5. Cancer Ameliorations and Cancer Immunity.
ARTHUR F. HOLDING, Madison, Wis.
6. The Treatment of Combined Diabetes and Nephritis.
FREDERICK M. ALLEN, J. W. MITCHELL and J. W. SHERRILL, New York.
7. Deficiencies in Our Methods of Treatment of Chronic Nephritis.
HENRY A. CHRISTIAN, Boston.
Discussion to be opened by LEWELLYS F. BARKER, Baltimore, and GEORGE DOCK, St. Louis.

Thursday, April 29—2 p. m.

JOINT MEETING OF SECTIONS ON PHARMACOLOGY AND THERAPEUTICS AND ON DERMATOLOGY

Meeting Place—Hutchinson Memorial Building,
Lower Amphitheater

OLIVER S. ORMSBY, Chairman of Section on Dermatology,
Presiding.

CARY EGGLESTON, Secretary of Section on Pharmacology and Therapeutics, Officiating.

SYMPOSIUM ON ARSPHENAMIN

8. The Chemical Composition of Arspenamin and Neo-Arsphenamin and Its Relation to Toxicity (Lantern Demonstration).
GEORGE W. RAIZISS, Philadelphia.
9. The Pathology of Arspenamin and Neo-Arsphenamin Intoxication: An Experimental Study (Lantern Demonstration).
JOHN A. KOLMER and BALDUIN LUCKE, Philadelphia.
10. Some Salient Facts Regarding the Toxicity of Arspenamin and Neo-Arsphenamin.
GEORGE B. ROTH, Washington, D. C.
11. A Comparison of the Merits of Arspenamin and Neo-Arsphenamin: Laboratory and Clinical Studies (Lantern Demonstration).
JAY F. SCHAMBERG, Philadelphia.
12. Therapeutic Applications and Limitations of the Arspenamins.
JOHN H. STOKES, Rochester, Minn.
13. Effects of Arspenamin on Renal Function in Syphilitic Patients.
JOSEPH A. ELLIOTT, Charlotte, N. C.
14. The Use of Arspenamin in Nonsyphilitic Diseases.
HENRY J. NICHOLS and MATHEW A. REASONER, Washington, D. C.
Discussion of papers 8, 9, 10, 11, 12, 13 and 14 to be opened by WILLIAM A. PUSEY, Chicago, and WILLIAM H. GUY, Pittsburgh.

Friday, April 30—9 a. m.

Election of Officers

15. The Underlying Pathology of Arthritis and Rheumatoid Conditions as a Basis of Treatment.
RALPH PEMBERTON, Philadelphia.
16. Factors Affecting the Basal Metabolic Rate (Lantern Demonstration).
LEONARD G. ROWNTREE, ALBERT M. SNELL and FRANCES FORD, Minneapolis.
17. Clinical Observations on the Digitalis-Like Action of Squills.
PAUL D. WHITE, Boston.
18. The Management of the Circulation in Pneumonia.
HARLOW BROOKS and JOHN H. CARROLL, New York.
Discussion to be opened by JOSEPH A. CAPPS, Chicago.
19. Quantitative Studies in Chemotherapy (Lantern Demonstration).
CARL VOEGTLIN and HOMER W. SMITH, Washington, D. C.

SECTION ON PATHOLOGY AND PHYSIOLOGY

MEETS IN GRUNEWALD—GREEN ROOM

OFFICERS OF SECTION

Chairman—HOWARD T. KARSNER, Cleveland.
Secretary—JOSIAH J. MOORE, Chicago.
Executive Committee—JAMES EWING, New York; LOUIS B. WILSON, Rochester, Minn.; FRANCIS CARTER WOOD, New York.
(Stenographer—Miss MARGARET I. MALONEY, Chicago)

Wednesday, April 28—2 p. m.

1. Chairman's Address: Teaching the Pathology of Function.
HOWARD T. KARSNER, Cleveland.
2. Increasing the Pathologist's Usefulness and Rewards.
BENJAMIN TAYLOR TERRY, Nashville, Tenn.
Discussion to be opened by JAMES EWING, New York; FRANCIS CARTER WOOD, New York, and WILLIAM C. MACCARTY, Rochester, Minn.
3. Experimental Pellagra in White Male Convicts.
JOSEPH GOLDBERGER and GEORGE A. WHEELER, Washington, D. C.
4. Review of the Recent Reports on Pellagra.
JAMES W. BABCOCK, Columbia, S. C.
5. The Pathology of Pellagra.
MARVIN L. GRAVES, Galveston, Texas.
Discussion of papers 3, 4 and 5 to be opened by MARTIN F. ENGMAN, St. Louis, and MARCUS HAASE, Memphis, Tenn.

6. Recent Advances in Clinical Blood Pressure Measurement.
CLYDE BROOKS and ALBERT M. BLEILE, Columbus, Ohio.
7. An Experimental Study of Acidosis Produced by Ether Anesthesia. WILLIAM S. CARTER, Galveston, Texas.

Thursday, April 29—2 p. m.

8. The Development of the Bactericidal Power of Whole Blood and of Antibodies in the Serum.
JAMES H. BLACK, Dallas, Texas.
9. Some Characteristics of Certain Epidemic Micro-Organisms.
DAVID J. DAVIS, Chicago.
10. The Toxic Substances Produced by Hemolytic Streptococci.
LUBVIG HEKTOEN, Chicago.
11. Penetration of the Intestine and Formation of Abdominal Abscess by Entameba Histolytica.
KENNETH M. LYNCH, Charleston, S. C.
12. Localization of Malarial Parasites in the Tissues.
CHARLES C. BASS, New Orleans.
13. A Mathematical Terminology for Neoplasia.
WILLIAM C. MACCARTY, Rochester, Minn.
14. Chronic Nephritis with Special Reference to the Interstitial Form.
LOUIS A. TURLEY, Norman, Okla.

Friday, April 30—2 p. m.**Election of Officers**

15. Bacterial Vaccines: Their Uses and Abuses.
ADELBERT M. MOODY, Chicago.
16. The Wassermann Reaction: Prolonged Incubation in the Icebox Versus a Short Period over the Water Bath.
WARD T. BURDICK, Denver.
17. The Value of the Postmortem Wassermann Reaction.
F. STUART GRAVES, Louisville, Ky.
Discussion to be opened by EDWIN R. LECOUNT, Chicago.
18. Observations on the Quantitative Nature of Complement Fixation.
JOHN J. SEELMAN, Milwaukee.
Discussion to be opened by JOHN A. KOLMER, Philadelphia.
19. The Complement Fixation Reaction in Tuberculosis.
W. WARNER WATKINS and CLARENCE N. BOYNTON, Phoenix, Ariz.
20. Transplantation of the Kidney and Ovary.
I. CARLETON DEDERER, Bay City, Mich.
21. Inhalations of Carbon Dioxid in Combating Postoperative Shock.
YANDELL HENDERSON and HOWARD W. HAGGARD, New Haven, Conn., and RAYMOND C. COBURN, New York.

SECTION ON STOMATOLOGY

MEETS IN HUTCHINSON MEMORIAL BUILDING,
FACULTY ROOM

OFFICERS OF SECTION

Chairman—VILRAY P. BLAIR, St. Louis.
Vice Chairman—HENRY S. DUNNING, New York.
Secretary—ARTHUR D. BLACK, Chicago.
Executive Committee—ARTHUR D. BLACK, Chicago; FREDERICK B. NOYES, Chicago; EUGENE S. TALBOT, Chicago.
(Stenographer—Mr. ARTHUR J. CHAPMAN, New Orleans)

Wednesday, April 28—2 p. m.

1. Chairman's Address. VILRAY P. BLAIR, St. Louis.
Discussion to be opened by G. V. I. BROWN, Milwaukee.
2. Emergency Splinting of Jaw Fractures: Intra-Oral Appliances. LEO B. WINTER, New York.
3. Emergency Splinting of Jaw Fractures: Extra-Oral Appliances.
WILLIAM C. SPEAKMAN, Wilmington, Del.
4. Treatment of Fractures of the Angle and Ramus.
J. D. EBY, Philadelphia.
5. Gradual Reduction of Fractures of the Maxilla and Mandible. A. L. MILLER, Fort McHenry, Md.
6. Treatment of Comminuted Fractures of the Mandible.
HERBERT A. POTTS, Chicago.
Discussion of papers 2, 3, 4, 5 and 6 to be opened by THOMAS L. GILMER, Chicago.

Thursday, April 29—2 p. m.

7. Epithelial Inlays versus Skin or Mucous Membrane Flaps for Replacing Lost Mucous Membrane in the Mouth.
GEORGE M. DORRANCE, Philadelphia.
8. Plastic Repair of Soft Tissue Injuries of the Face.
J. D. WHITHAM, Washington, D. C.
9. Final Report of War Cases of Comminuted Open Fractures of the Jaws and Those with Loss of Substance: Results of Bone Graft. ROBERT H. IVY, Philadelphia.
Discussion to be opened by M. I. SCHAMBERG, New York.
10. Adenoma of the Mucous Glands of the Mouth and Macrocheilia.
EDWARD H. HATTON, Chicago.
Discussion to be opened by FREDERICK B. MOOREHEAD, Chicago.
11. Surgical Treatment of Maxillary Sinusitis of Dental Origin.
HENRY S. DUNNING, New York.
Discussion to be opened by HERBERT A. POTTS, Chicago.

Friday, April 30—2 p. m.**Election of Officers**

12. Progress in Dental Education.
H. E. FRIESEL, Pittsburgh.
Discussion to be opened by EUGENE S. TALBOT, Chicago.
13. Dental Care of Children in Our Hospitals.
HAIDEE WEEKS GUTHRIE, New Orleans.
14. Training Public Schoolchildren in Mouth Hygiene.
A. C. FONES, Bridgeport, Conn.
15. Public Education in Mouth Hygiene.
OTTO U. KING, Chicago.
Discussion of papers 13, 14 and 15 to be opened by ARTHUR D. BLACK, Chicago.

SECTION ON NERVOUS AND MENTAL DISEASES

MEETS IN CHARITY HOSPITAL, AMPHITHEATER

OFFICERS OF SECTION

Chairman—ELMER E. SOUTHARD,* Boston.
*Deceased.
Vice Chairman—ARTHUR S. HAMILTON, Minneapolis.
Secretary—CHARLES W. HITCHCOCK, Detroit.
Executive Committee—BERNARD SACHS, New York; CHARLES EUGENE RIGGS, St. Paul; ARCHIBALD CHURCH, Chicago.
(Stenographer—Miss ADELAIDE FOLSOM, Ripon, Wis.)

Wednesday, April 28—9 a. m.

1. Chairman's Address. ARTHUR S. HAMILTON, Minneapolis.
2. Reduction of Nervous Irritability and Excitement by Progressive Relaxation. EDMUND JACOBSON, Chicago.
3. Influenza and Feeble-mindedness. KARL A. MENNINGER, Topeka, Kan.
4. Conjugal Syphilis of the Nervous System. ALFRED GORDON, Philadelphia.
5. Discussion of Therapeutic Agents in Chronic Nervous Diseases. WILLIAM A. JONES, Minneapolis.
6. Congenital Facial Paralysis: Two Additional Cases. FRANK R. FRY, St. Louis.
7. The Causes of Emotivity and Their Management. TOM A. WILLIAMS, Washington, D. C.

Thursday, April 29—9 a. m.

8. A Theory of the Neuroses as Instinctive Reactions. SIDNEY I. SCHWAB, St. Louis.
9. Prognosis of Traumatic Neurosis. LOUIS A. MILLER, Toledo, Ohio.
10. Experiences with Luminal in Epilepsy. JULIUS GRINKER, Chicago.
11. The Paraplegic Type of Multiple Sclerosis. ARCHIBALD CHURCH, Chicago.
12. Endocrine Imbalance in the Feeble-minded. OSCAR J. RAEDER, Boston.
13. The Amnesias in Head Injuries. HAROLD N. MOYER, Chicago.
14. The Physiologic Significance of the Babinski Toe Response. I. LEON MEYERS, Chicago.

Friday, April 30—9 a. m.**Election of Officers**

15. Nervous and Mental Diseases: A Challenge to the Medical Profession. FRANKWOOD E. WILLIAMS, New York.

16. Symptomatology of Spinal Cord Tumors with Illustrative Cases.
I. ABRAHAMSON and H. CLIMENKO, New York.
17. The Physician and the Neuropath.
CHARLES R. BALL, St. Paul.
18. Outline of a Scheme for Writing the Natural History of Syphilis.
SANGER BROWN, Chicago.
19. Measles: Brain Complications.
A. L. SKOOG, Kansas City, Mo.
20. The Relation of Worms to Epilepsy.
E. BATES BLOCK, Atlanta, Ga.
21. Encephalitis Lethargica.
EDWARD LIVINGSTON HUNT, New York.

SECTION ON DERMATOLOGY

MEETS IN HUTCHINSON MEMORIAL BUILDING,
LOWER AMPHITHEATER

OFFICERS OF SECTION

Chairman—OLIVER S. ORMSBY, Chicago.
Vice Chairman—JOHN E. LANE, New Haven, Conn.
Secretary—WALTER J. HIGHMAN, New York.
Executive Committee—HENRY R. VARNEY, Detroit; HENRY H. HAZEN, Washington, D. C.; OTTO H. FOERSTER, Milwaukee.
(Stenographer—Mrs. IRENE H. SNYDER, Chicago)

Wednesday, April 28—2 p. m.

1. Chairman's Address: A Valuable Method of Employing Arsphenamin in Syphilis.
OLIVER S. ORMSBY, Chicago.

SYMPOSIUM ON SYPHILIS

2. Polyneuritis Plus Dermatitis Exfoliativa Following Neo-Arsphenamin.
B. BARKER BEESON, Chicago.
3. Arsphenamin Dermatitis.
GEORGE M. OLSON, Minneapolis.
4. A Study of the Absorption of Mercury Injections by Means of the Roentgen Ray.
HAROLD N. COLE, Cleveland.
5. The Value of the Provocative Wassermann Test in the Diagnosis of Obscure Syphilis.
PAUL A. O'LEARY, Rochester, Minn.
6. Protein Sensitization in Eczema.
HOWARD FOX, New York, and J. EDGAR FISHER, Pittsburgh.
7. Infections Eczematoid Dermatitis.
RICHARD L. SUTTON, Kansas City, Mo.
8. Eczema of the Vermilion Border of the Lips.
DOUGLASS W. MONTGOMERY and GEORGE D. CULVER, San Francisco.
9. Venipuncture as an Occasional Adjuvant in the Treatment of Certain Diseases of the Skin.
JEROME KINGSBURY and PAUL E. BECHET, New York.

Thursday, April 29—2 p. m.

JOINT MEETING OF SECTIONS ON PHARMACOLOGY AND
THERAPEUTICS AND ON DERMATOLOGY

SYMPOSIUM ON ARSPHENAMIN

For Program See Page 855

Friday, April 30—2 p. m.

Election of Officers

SYMPOSIUM ON NEW GROWTHS

17. A Clinical Study of Epitheliomas of the Lower Lip (Lantern Demonstration).
EVERETT S. LAIN, Oklahoma City.
18. Malignant Degeneration of Benign Dermatoses.
CHARLES M. WILLIAMS, New York.
19. Malignant Tumors of the Skin.
EARL D. CRUTCHFIELD, Galveston, Texas.
20. On Production of Tumors in the Absence of Parasites.
ERWIN F. SMITH, Washington, D. C.
21. The Treatment of Keloid and Hypertrophied Scars by Radiotherapy Alone or Combined with Excision.
GEORGE E. PFAHLER, Philadelphia.
Discussion of papers 17, 18, 19, 20 and 21 to be opened by NORMAN WALKER, Edinburgh.
22. Acidosis in Skin Diseases.
SAMUEL E. SWEITZER and HENRY E. MICHELSON, Minneapolis.

23. Lichen Spinulosus and Folliculitis Decalvans: A Clinical Combination.
FRANCIS E. SENEAR, Chicago.
24. The Association of Herpes Zoster and Varicella.
ERNEST L. McEWEN, Chicago.
25. The Histogenesis of Molluscum Contagiosum (Lantern Demonstration).
LYLE B. KINGERY, Ann Arbor, Mich.

SECTION ON PREVENTIVE MEDICINE AND PUBLIC HEALTH

MEETS IN LOYOLA HALL

OFFICERS OF SECTION

Chairman—JAMES A. HAYNE, Columbia, S. C.
Vice Chairman—J. D. MACLEAN, Harrisburg, Pa.
Secretary—CLARENCE D. SELBY, Toledo, Ohio.
Executive Committee—OTTO P. GEIER, Cincinnati; W. S. RANKIN, Raleigh, N. C.; CLARENCE ST. CLAIR DRAKE, Springfield, Ill.
(Stenographer—Mrs. M. C. REPP, Philadelphia)

Wednesday, April 28—9 a. m.

1. Chairman's Address: The Rights of the Child.
JAMES A. HAYNE, Columbia, S. C.
2. What the American Red Cross Can Contribute to the General Health Program.
ERWIN A. PETERSON, Washington, D. C.
3. Mortality and Incidence of Leprosy Throughout the World.
FREDERICK L. HOFFMAN, Newark, N. J.
Discussion to be opened by ISADORE DYER, New Orleans.
4. Desirable Trend of National Health Policies.
BENJAMIN S. WARREN, Washington, D. C.
5. Minimum Standards of Organization for Municipal Health Departments.
CARROLL FOX, Boston.
6. Sanitation in Poland.
FRANCIS E. FRONCZAK, Buffalo.
7. The Training of Industrial Physicians.
J. A. WATKINS, Cincinnati.
Discussion to be opened by OTTO P. GEIER, Cincinnati.

Thursday, April 29—9 a. m.

8. The Carrier Question in Epidemic Meningitis and Diphtheria.
CHARLES M. ABBOTT, Alexandria, La.
9. Typhoid Reduction in South Carolina: Results in Counties with Health Organization.
LUTHER A. RISER, Columbia, S. C.
Discussion to be opened by KNOX E. MILLER, Raleigh, N. C.
10. Heart Disease as a Public Health Problem.
LEWIS A. CONNER, New York.
Discussion to be opened by ALEXANDER LAMBERT, New York.
11. Eradication of Malaria: A National Health Problem.
LUNSFORD D. FRICKS, Memphis, Tenn.
12. Trachoma: A Public Health Problem of the States (Lantern Demonstration).
JOHN McMULLEN, Louisville, Ky.
Discussion to be opened by ARTHUR T. McCORMACK, Louisville, Ky., and ALLEN W. FREEMAN, Columbus, Ohio.
13. Industrial Epidemiology.
W. A. SAWYER, Rochester, N. Y.

Friday, April 30—9 a. m.

Election of Officers

14. The Work of the Department of Health of the Tennessee Coal, Iron and Railroad Company.
LLOYD NOLAND, Birmingham, Ala.
Discussion to be opened by CLYDE E. FORD, New York.
15. The Difficulties of Public Health Administration.
GROVER C. MCKINNEY, Lake Charles, La.
16. An Ambulatory Clinic.
RALPH N. GREENE, Jacksonville, Fla.
17. Lessons Taught by Measures for Control of Venereal Diseases and Suggestions for the Future.
CLAUDE C. PIERCE, Washington, D. C.
18. The Necessity for the Reporting of Venereal Disease by Physicians.
WILLIAM EDLER, New Orleans.
Discussion to be opened by OSCAR DOWLING, New Orleans.
19. The Differential Diagnosis of Conjunctival Folliculosis and Trachoma.
J. WILKINSON JERVEY, Greenville, S. C.
Discussion to be opened by HENRY DICKSON BRUNS, New Orleans, and THEODORE OERTEL, Augusta, Ga.

SECTION ON UROLOGY

MEETS IN HUTCHINSON MEMORIAL BUILDING,
LOWER AMPHITHEATER

OFFICERS OF SECTION

Chairman—WILLIAM E. LOWER, Cleveland.

Vice Chairman—RICHARD F. O'NEIL, Boston.

Secretary—E. O. SMITH, Chicago.

Executive Committee—HUGH CABOT, Ann Arbor, Mich.;
EDWARD L. KEYES, JR., New York; WILLIAM F. BRAASCH,
Rochester, Minn.

(Stenographer—Mrs. IRENE H. SNYDER, Chicago)

Wednesday, April 28—9 a. m.

1. Chairman's Address: Disposition of the Ureter in Surgical Conditions of the Bladder Involving the Ureteral Orifices. WILLIAM E. LOWER, Cleveland.
2. Results of Surgical Treatment of Tumors of the Bladder. E. STARR JUDD and WALTER E. SISTRUNK, Rochester, Minn.
3. Radium Treatment of Bladder Carcinoma. BENJAMIN S. BARRINGER, New York.
4. Bladder Tumors: Pathology and Radiumtherapy. JOHN T. GERAGHTY, Baltimore.
5. The Treatment of Bladder Tumors with Analysis of Cases. BENJAMIN A. THOMAS, Philadelphia. Discussion of papers 2, 3, 4 and 5 to be opened by LOUIS E. SCHMIDT, Chicago, EDWARD L. KEYES, New York, and HUGH CABOT, Ann Arbor, Mich.
6. Papillomatous Epithelioma of Kidney Pelvis. PERCY E. McCOWN, Indianapolis. Discussion to be opened by E. STARR JUDD, Rochester, Minn., and WILLIAM E. LOWER, Cleveland.

Thursday, April 29—9 a. m.

7. Abdominal Pain in Diseases of the Kidney and Ureters. ARTHUR B. CECIL, Los Angeles. Discussion to be opened by ALFRED I. FOLSOM, Dallas, Texas.
8. Studies of Pyelitis in Infancy. HERMAN L. KRETSCHMER, Chicago. Discussion to be opened by WILLIAM C. QUINBY, Boston, and WILLIAM F. BRAASCH, Rochester, Minn.
9. Nephrectomy: Based on the Record of 250 Cases. ABRAHAM HYMAN and EDWIN BEER, New York. Discussion to be opened by ALEXANDER RANDALL, Philadelphia.
10. Ureteral Obstruction and Dilatation in the Male. ALBERT E. GOLDSTEIN, Baltimore. Discussion to be opened by BRANSFORD LEWIS, St. Louis, and JOHN G. KELLER, Toledo, Ohio.
11. Occluded Renal Tuberculosis (Lantern Demonstration). WILLIAM F. BRAASCH, Rochester, Minn. Discussion to be opened by JOSEPH HUME, New Orleans.
12. Developmental Factors in the Formation of Certain Vesical Diverticula (Lantern Demonstration). ERNEST M. WATSON, Buffalo. Discussion to be opened by OSWALD S. LOWSLEY, New York.
13. Diverticulum of the Bladder (Lantern Demonstration). FRANCIS M. McCALLUM, Kansas City, Mo. Discussion to be opened by COURTNEY W. SHROPSHIRE, Birmingham, Ala.

Friday, April 30—9 a. m.

Election of Officers

14. Contraindications to Prostatectomy (Lantern Demonstration). JAMES A. GARDNER, Buffalo. Discussion to be opened by HUGH H. YOUNG, Baltimore.
15. Ulcer of the Bladder—Hunner Type. HARRY A. FOWLER, Washington, D. C. Discussion to be opened by GUY L. HUNNER, Baltimore.
16. Bladder Findings in Central Nervous System Diseases. JOHN R. CAULK, St. Louis. Discussion to be opened by BUDD C. CORBUS, Chicago, and HARRY W. PLACEMAYER, Detroit.
17. Urological and Venereal Idiosyncrasies in the Negro. GEORGE H. DAY, Louisville. Discussion to be opened by CARL L. WHEELER, Lexington, Ky.

18. Gonorrhea of the Lower Genito-Urinary Tract in Women, with Special Reference to the Glands of Bartholin. WILLIAM E. STEVENS and MAURICE HEPPNER, San Francisco.

Discussion to be opened by GEORGE G. SMITH, Boston, and RUFUS L. RIGDON, San Francisco.

19. Orchitis from Mumps: Conservation of the Testes by Incision of the Tunica Albuginea.

EDGAR G. BALLENGER, Atlanta, Ga.
Discussion to be opened by FRANCIS R. HAGNER, Washington, D. C.

20. Spermatogenesis in Relation to Childlessness (Lantern Demonstration).

VICTOR D. LESPINASSE, Chicago.
Discussion to be opened by MAX HUHNER, New York.

SECTION ON ORTHOPEDIC SURGERY

MEETS IN CHARITY HOSPITAL, AMPHITHEATER

OFFICERS OF SECTION

Chairman—GEORGE W. HAWLEY, New York.

Vice Chairman—ROLAND HAMMOND, Providence, R. I.

Secretary—HENRY BASCOM THOMAS, Chicago.

Executive Committee—EDWIN W. RYERSON, Chicago; ALBERT H. FREIBERG, Cincinnati; EMIL S. GEIST, Minneapolis.

(Stenographer—Miss ADELAIDE FOLSOM, Ripon, Wis.)

Wednesday, April 28—2 p. m.

1. Orthopedic Conditions Directly Due to Sterilized Food in Infancy (Lantern Demonstration). FRANK E. PECKHAM, Providence, R. I. Discussion to be opened by MAURICE L. BLATT, Chicago, and EDWARD S. HATCH, New Orleans.
2. Operations for Repair of Bone Defects: Results Obtained at Letterman General Hospital (Lantern Demonstration). LEO ELOESSER, San Francisco. Discussion to be opened by J. PAUL JONES, Camden, Ala.
3. Results of Bone Graft at U. S. Army Hospital No. 3 (Lantern Demonstration). JOHN SPENCER DAVIS, Dallas, Texas, and JACOB J. SYBENGA, Pella, Iowa. Discussion to be opened by PAUL B. MAGNUSON, Chicago, and ERASMUS D. FENNER, New Orleans.

SYMPOSIUM ON TREATMENT OF INFANTILE PARALYSIS

4. Transverse Horizontal Section of the Tarsus in Paralytic Calcaneus and Flail Foot (Lantern Demonstration). DEFOREST P. WILLARD, Philadelphia.
5. Operative Treatment of Infantile Paralysis. ROBERT W. LOVETT, Boston.
6. Indications for and End-Results of Surgical Operations in Infantile Paralysis (Lantern Demonstration). H. WINNETT ORR, Lincoln, Neb.
7. Sling Suspension Method of Exercises in Infantile Paralysis (Lantern Demonstration). FREDERICK J. GAENSLEN, Milwaukee. Discussion of papers 4, 5, 6 and 7 to be opened by JOHN D. RIDLON, Chicago; FRANK D. DICKSON, Kansas City, Mo.; JAMES O. WALLACE, Pittsburgh; WILLIS K. WEST, Oklahoma City; ARTHUR STEINDLER, Iowa City; CLARENCE W. EAST, Springfield, Ill.; PHILIP D. WILSON, Boston, and HENRY B. THOMAS, Chicago.

Thursday, April 29—2 p. m.

8. Anterior Bow-Legs. WALLACE BLANCHARD, Chicago. Discussion to be opened by WILLIS C. CAMPBELL, Memphis, Tenn., and H. WINNETT ORR, Lincoln, Neb.
9. Chairman's Address: Constructive Versus Reconstructive Surgery of the Extremities. ROLAND HAMMOND, Providence, R. I.
10. Some of the Difficulties in the Diagnosis of Osteosarcoma (Lantern Demonstration). ROBERT B. COFIELD, Cincinnati. Discussion to be opened by DEAN D. LEWIS, Chicago, and FREDERICK J. GAENSLEN, Milwaukee.
11. Dislocation of the Carpal Semilunar Bone (Lantern Demonstration). WALTER G. STERN, Cleveland. Discussion to be opened by SAMUEL KLEINBERG, New York, and EDWARD S. HATCH, New Orleans.

12. Recurrent Dislocations and Allied Chronic Conditions of the Shoulder. T. TURNER THOMAS, Philadelphia. Discussion to be opened by WILLIAM J. MERRILL, Philadelphia; MELVIN S. HENDERSON, Rochester, Minn., and ALFRED C. WOOD, Philadelphia.
13. The Objective Symptoms of Foot Strain (Lantern Demonstration). ALBERT H. FREIBERG, Cincinnati. Discussion to be opened by JOHN L. PORTER, Chicago, and JOHN CARLING, Los Angeles.
14. Unstandardized Versus Standardized Splints. HORACE R. ALLEN, Indianapolis. Discussion to be opened by CLARENCE W. HOPKINS, Chicago.

Friday, April 30—2 p. m.

Election of Officers

15. Operative Treatment of Peripheral Nerve and Associated Bone Lesions in One Stage. JOHN O. BOWER, Philadelphia. Discussion to be opened by WILLIAM W. BARCOCK, CHARLES H. FRAZIER, Philadelphia, and HARRY HYLAND KERR, Washington, D. C.

SYMPOSIUM ON RESTORATION OF THE DISABLED

16. Restoration of the Disabled in War as Applied to Industrial Disability. ELLIOTT G. BRACKETT, Boston.
17. Reclamation Service for Workmen Permanently Handicapped in Industry. HARRY E. MOCK, Chicago.
18. Progress in the Care of Cripples. CARROLL L. STOREY, Detroit. Discussion of papers 16, 17 and 18 to be opened by CLARENCE ST. CLAIR DRAKE, Springfield, Ill.; ALBERT H. FREIBERG, Cincinnati; JOHN T. O'FERRALL, New Orleans, FRANK G. MURPHY, Chicago, and FREDERICK C. KIDNER, Detroit.
19. Intra-Articular Fractures. ROBERT D. SCHROCK, Omaha. Discussion to be opened by PAUL A. McILHENNY, New Orleans; HENRY C. MARBLE, Boston; NATHANIEL ALLISON, St. Louis, and NORMAN KERR, Chicago.
20. The Occurrence and Causes of Functional Scoliosis in College Men. WILLIAM L. ESTES, South Bethlehem, Pa. Discussion to be opened by ROBERT W. LOVETT, Boston, and EDWIN W. RYERSON, Chicago.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

MEETS IN LOYOLA HALL

OFFICERS OF SECTION

Chairman—FRANK SMITHIES, Chicago.
Vice Chairman—LOUIS J. HIRSCHMAN, Detroit.
Secretary—HORACE W. SOPER, St. Louis.
Executive Committee—DWIGHT H. MURRAY, Syracuse, N. Y.; ANTHONY BASSLER, New York; WILLIAM M. BEACH, Pittsburgh.
(Stenographer—Mrs. M. C. REPP, Philadelphia)

Wednesday, April 28—2 p. m.

1. Chairman's Address: The Significance of Etiologic Factors in the Treatment of Peptic Ulcer. FRANK SMITHIES, Chicago.
2. Principles of Gastric Analysis. MARTIN E. REHFUSS, Philadelphia. Discussion to be opened by ANTHONY BASSLER and G. A. FRIEDMAN, New York.
3. Fractional Gastric Analyses. GEORGE REESE SATTERLEE, New York, and WALTER B. JENNINGS and HENRY A. COTTON, Trenton, N. J. Discussion to be opened by BURRILL B. CROHN, New York; MARTIN E. REHFUSS, Philadelphia, and JOHN P. SAWYER, Cleveland.
4. The Differential Diagnosis of Amebiasis, Tuberculosis, Syphilis and Carcinoma as Manifested in the Rectum and Pelvic Colon. J. RAWSON PENNINGTON, Chicago. Discussion to be opened by CHARLES J. DRUECK, Chicago; CHARLES E. HYNDMAN, St. Louis, and HOLLAND H. DONALDSON, Pittsburgh.
5. Hemorrhoidectomy: Composite Operation. EDWARD G. MARTIN, Detroit. Discussion to be opened by LOUIS J. KROUSE, Cincinnati; JAMES A. DUNCAN, Toledo, Ohio, and GEORGE W. COMBS, Indianapolis.

6. Diverticula of the Small Intestines other than Meckel's Diverticulum. JAMES T. CASE, Battle Creek, Mich. Discussion to be opened by WILLIAM J. MAYO, Rochester, Minn., and DUBLEY D. ROBERTS, New York.
7. Hypotension Headache in Relation to Constipation. ERNEST CLYDE FISHBAUGH, Los Angeles. Discussion to be opened by ALBERT BERNHEIM, Philadelphia; JOHN D. DUNHAM, Columbus, Ohio, and ELSWORTH S. SMITH, St. Louis.

Thursday, April 29—2 p. m.

8. Further Studies on Gastric and Duodenal Ulcer. A. C. IVY, Chicago. Discussion to be opened by CHARLES H. NEILSON, St. Louis, and WALTER C. ALVAREZ, San Francisco.
9. Gastrojejunal Ulcer: Clinical Study of Eighty-Four Cases. GEORGE B. EUSTERMANN, Rochester, Minn. Discussion to be opened by JULIUS FRIEDENWALD, Baltimore; CHARLES H. MAYO, Rochester, Minn., and WILLARD BARTLETT, St. Louis.
10. Critical Review of 500 Cases of Gastric and Duodenal Ulcer. ELMER L. EGGLESTON, Battle Creek, Mich. Discussion to be opened by JAMES TAFT PILCHER, Brooklyn, and SIDNEY K. SIMON, New Orleans.
11. Specialization in the Medical and Surgical Treatment of Ulcer of the Stomach and Duodenum. ANGELO L. SORESI, New York. Discussion to be opened by CHARLES D. AARON, Detroit, and E. STARR JUDD, Rochester, Minn.
12. Insufficiency of the Cardia. JOSEPH SAILER, Philadelphia. Discussion to be opened by HARRY G. WALCOTT, Dallas, Texas; EDWARD H. SKINNER, Kansas City, Mo., and SEALE HARRIS, Birmingham, Ala.
13. Rectocolonic Therapy. ALFRED J. ZOBEL, San Francisco. Discussion to be opened by LOUIS J. HIRSCHMAN, Detroit; WILLIAM M. BEACH, Pittsburgh; DWIGHT H. MURRAY, Syracuse, N. Y., and J. RAWSON PENNINGTON, Chicago.
14. The Evidence in Favor of Water Drinking with Meals. ELBRIDGE G. CUTLER, Boston. Discussion to be opened by JOHN M. BELL, St. Joseph, Mo.; ERNEST ZUEBLIN, Cincinnati, and JOHN W. BELL, Minneapolis.

Friday, April 30—2 p. m.

Election of Officers

15. Mucous Colitis. WILLIAM H. STAUFFER, St. Louis. Discussion to be opened by J. DAWSON REEDER, Baltimore; JOHN M. FRICK, Toledo, Ohio, and J. COLES BRICK, Philadelphia.
16. Modification of Intestinal Flora. J. RUSSELL VERBRYCKE, JR., Washington, D. C. Discussion to be opened by WILLIAM GERRY MORGAN, Washington, D. C., and ANTHONY BASSLER, New York.
17. Arthritic Changes in the Spine and Their Relation to the Roentgenologic Study of the Gastro-Intestinal Tract. WILLIAM S. NEWCOMET, Philadelphia. Discussion to be opened by SHERWOOD MOORE, St. Louis; JAMES T. CASE, Battle Creek, Mich., and JOHN BRYANT, Boston.
18. What Is Being Done for the Insane by Means of Surgery. JOHN W. DRAPER, New York. Discussion to be opened by HENRY A. COTTON, Trenton, N. J., and JEROME M. LYNCH, New York.
19. The Roentgenology of the Appendix: The Significance of the Opaque Filling in Chronic Appendicitis. EDWARD H. SKINNER, Kansas City, Mo. Discussion to be opened by R. WALTER MILLS, St. Louis; GEORGE E. PFAHLER, Philadelphia, and MARSH FITZMAN, St. Louis.
20. Visualization of the Duodenum by Means of the Duodenal Tube. ISRAEL D. PALEFSKI, New York. Discussion to be opened by MAX EINHORN, New York, and CLEMENT R. JONES, Pittsburgh.
21. The Treatment of the Chronic Intestinal Invalid. JOHN BRYANT, Boston. Discussion to be opened by JEROME M. LYNCH and JOHN W. DRAPER, New York, and J. C. JOHNSON, Atlanta, Ga.
22. Diaphragmatic Hernia Diagnosed During Life. M. MILTON PORTIS and SIDNEY A. PORTIS, Chicago. Discussion to be opened by GEORGE E. PFAHLER, Philadelphia, and LEWIS GREGORY COLE and SEYMOUR BASCH, New York.

THE EXHIBITS—ALLONS!

"Allons," said Dr. Voolayvoo, as the discussion of the last paper of the first morning dwindled to a close, "let us depart quickly from here."

"Why the haste?" I asked.

"The exhibits, the exhibits, my friend. Do you not know that in them is enough of interest to occupy our full time all of this week? We must arrive there before the crowd. I know of no other feature of this magnificent gathering that offers more to the physician than these exhibits."

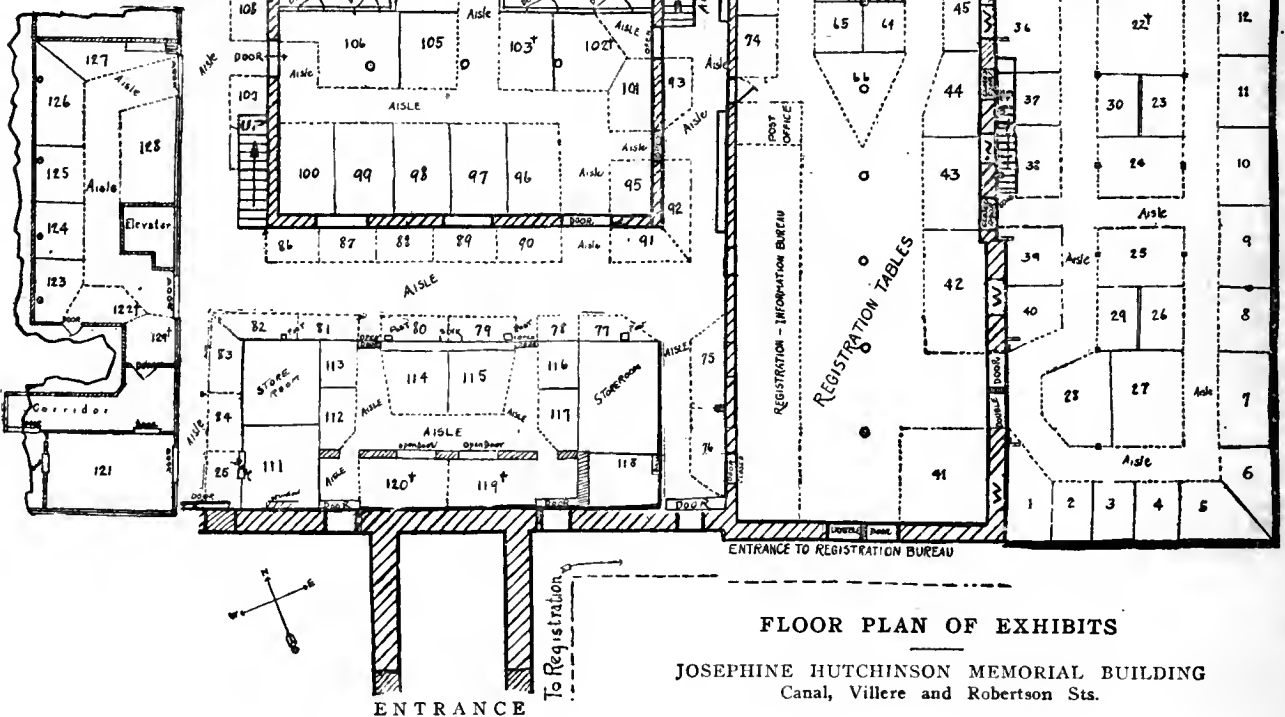

"You mean the free samples?" I queried.

"Oh, non, non, vous ne-comprenez-pas," said Dr. Voolayvoo, witheringly, and I knew I had made a faux pas. "It is not the material things, valuable though they may be, but

rather the new ideas one finds at these commercial exhibits that make them of value."

"But, I really don't want to buy anything," said I weakly.

"Ma foi, that is not necessary," answered Voolayvoo. "Perhaps you have been wrongly impressed by that word

FLOOR PLAN OF EXHIBITS

JOSEPHINE HUTCHINSON MEMORIAL BUILDING
Canal, Villere and Robertson Sts.

List of Exhibitors

Exhibitor	Space No.	Exhibitor	Space No.	Exhibitor	Space No.
Abbott Laboratories, The, Chicago	10-11	Eastman Kodak Co., Rochester, N. Y.	10-11	Mueller & Co., V., Chicago	60-61-62-63
Allison Co., W. D.	85-111	Everhart, Laurence, Atlanta	107	Nelson & Son, Thos., New York	96-97
Aloe Co., A. S.	68-69-70-71	Fischer & Co., H. G., Chicago	14	Oxford University Press, New York	64-65-66
American Surgical Specialty Co., Chicago	33	Foregger Co., The, New York	119	Patterson Screen Co., Towanda, Pa.	21
Anatomik Footwear Co., New York	99	Fraas, Aug. E., New York	81	Pulvola Chemical Co., Jersey City, N. J.	90
Appleton & Co., D., New York	91-92	General Electric Co., Schenectady	106	Radin Chem. Corp., New York	122-123
Armour & Co., Chicago	7	Hanovia Chem. Co., Newark, N. J.	22	Radium Chemical Co., Pittsburgh	54-67
B. B. Culture Laboratory, Yonkers, N. Y.	2	Hardy & Co., F. A., Chicago	59	Radium Co. of Colorado, The, Denver	26-29
Bard-Parker Co., New York	25	Heyden Chem. Wks., New York	47	R. & E. Mfg. Co., The, Cleveland	78
Baum Co., Inc., Wm. A., New York	95	Hoerber, Paul B., New York	3	Safety Anesthesia App. Concern, Chicago	115
Bausch & Lomb Optic Co., Rochester, N. Y.	6	Hollister-Wilson Lab., Chicago	4	Sanborn Co., Boston	93
Becton-Dickinson Co., Rutherford, N. J.	20	Horlick's Malted Milk Co., Racine, Wis.	39-40	Saunders Co., W. B., Philadelphia	42
Berger Bros. Co., New Haven, Conn.	23-30	Hynson, Westcott & Dunning, Baltimore	37-38	Scientific App. Co., N. Y.	101
Betz Co., Frank S., Hammond, Ind.	19-31-32	Jaech, Mfg. Co., Cincinnati, Ohio	89	Sealy Mattress Co., Sugarland, Tex.	118
Blakiston's Son & Co., P., Philadelphia	43	Johnson & Co., Mead, Evansville, Ind.	105	Sorensen Co., Inc., C. M., New York	102-103
Boehm Surgical Inst. Co., Rochester, N. Y.	127	Kelley Koett Co., Covington, Ky.	12-13	Southworth Co., The, Troy, N. Y.	84
Brady & Co., Geo. W., Chicago	8	Kny-Scheerer Co., New York	128	Squibb & Sons, E. R., New York	27-28
Buzzell Chemicals Co., Boston	112-113	Leitz, E. Inc., New York	100	Takamine Laboratories, Inc., New York	98
Caleo Chemical Co., The, New York	114	Linen Underwear Co., Greenwich, Conn.	108	Taylor Instr. Cos., Rochester, N. Y.	24
Campbell Electric Co., Lynn, Mass.	121	Lippincott Co., J. B., Philadelphia	41	Thompson-Plaster Co., Leesburg, Va.	15
Chicago Medical Book Co., Chicago	45	Lungmotor Co., Boston	79-80	Thor Corporation, The, Chicago	104
Crain Publishing Co., Chicago	86	Lyons & Co., I. L., New Orleans	109	Toledo Technical App. Co., Toledo	116-117
Cummings Chem. Co., W. L., Lansdowne, Pa.	77	Malthie Chemical Co., Newark, N. J.	50-51	Victor Electric Corporation, Chicago	34-35-36
Davis Co., F. A., Philadelphia	9	Marshalltown Lab., Marshalltown, Ia.	82	Waterproof Fabric Co., Chicago	88
Dennison Mfg. Co., Framingham, Mass.	5	McDermott S. Ins. Co., N. Orleans	124-125-126	Weder Mfg. Co., Philadelphia	46
Dennos Products Co., Chicago	75	Mellin's Food Co., Boston	55-56-57-58	Welch Grape Juice Co., The, Westfield N.Y.	52
DeVilbiss Mfg. Co., The, Toledo	44	Metz Laboratories, H. A., New York	18	Wilson & Wilson, Boston	83
Dry Milk Co., The, New York	76	Meyrowitz, Inc., E. B., New York	16-17	Wood & Co., Wm., New York	48-49
Earnshaw Knitting Co., Chicago	53	Mushy Co., C. V., St. Louis	72-73-74	Year Book Publishers, Chicago	87

'commercial.' You must understand, my friend, that these exhibit gentlemen are here to serve us, to show us new ideas, new and better ways of doing things—and with all due respect to the intelligence of our noble profession, I may add—to help us."

"All right, let's go, then," I said.

WITHOUT RESERVATIONS

Dr. Voolayvoo was right. He seemed to be an "old timer" conventionist. I, being a novitiate, placed myself implicitly under his guidance. When we stepped into the Exhibit Hall I guess I looked like a child gazing at a Christmas tree—so many things, I simply stared. I was brought back to earth by the sound of my friend's voice. "Is it not wonderful," said he, "to see so much all in one unified exhibition arranged solely for the benefit of ourselves and our colleagues?"

"It sure is," I replied. "But, how in the world are we going to see it all?"

"Listen to me, my friend," said the Doctor, "we cannot see it all in one trip around. But we could ill afford to miss any one of these exhibits. Take my advice and concentrate on one exhibit at a time. And then you must come back tomorrow and each of the remaining days. Ah, voila, right before us is the Saunders exhibit."

"Say, I've been reading the announcements of those new Saunders books. Wonder if they have them here," I said.

BOOKS BOOKS BOOKS

They surely had—it was a regular bookstore. Warbasse's "Surgical Treatment," Burton-Opitz' "Textbook of Physiology," Mock's "Industrial Medicine and Surgery," the new "Mayo Clinic Volume," Dunton's "Reconstruction Therapy," and all the others were there. I could have camped at that exhibit alone for a good half day. But just across the aisle was another attractive book exhibit which I knew I must see—that of the Lippincott Company, and I also remembered some of the other book men who, too, would doubtless have attractive exhibits.

The Lippincott books were conveniently arranged for quick reference, and included a large line of practical medical, pharmaceutical and nursery texts. A courteous representative called our special attention to Buckley's "The Basis of Psychiatry," Sharp's long-wanted volume on "Brain Injuries," and Wilson and Potter's "Internal Medicine." Also, we could not deny ourselves the privilege of studying the splendid collection of fifty hand-colored Anatomical Charts from Pier-sol's "Human Anatomy."

CULTURE—THE B. B. KIND

Leaving the book exhibits, we stopped to examine the exhibit of the the B. B. Culture Laboratory. "This preparation I find very useful as a biological antiseptic for both internal and external uses," said Voolayvoo. "What, you have not yet tried it? Indeed, you must leave your name and address and have a complimentary bottle sent you."

"Happy thought," said I, "but now tell me who is the tall brunette gentleman in this next booth?"

"That, my friend, is Paul B. Hoeber. You have heard of 'The American Journal of Roentgenology,' the 'Annals of Medical History' and the 'Neurological Bulletin.' n'est-ce-pas? Mr. Hoeber publishes these journals and is showing them here." We stopped and besides these different journals I found some very interesting books, one of which I had been wanting for some time—Mackenzie's "Symptoms and Their Interpretations." So I ordered a copy right then and there.

EVERYTHING BUT GOAT GLANDS

"Do you employ the animal derivatives such as corpus luteum, pituitary extract, thyroids, etc., in your practice?" asked my guide and conductor as we passed on. "If so, you must not fail to see this interesting exhibit by the Hollister-Wilson Laboratories." He was right. Not until then did I realize how exacting were the requirements for producing dependable animal derivatives. I was specially interested in the set of original specimens showing the different phases of production in this field.

Proceeding farther, we stopped at the Bausch & Lomb exhibit, Space 6, where trained, scientific men were demon-

strating physicians' microscopes, a new model microtome, ophthalmological apparatus and hemacytometers of B. & L. manufacture. This was an opportunity I welcomed, for I have been thinking for some time I ought to have a microscope. The B. & L. instrument appealed to me strongly.

In the next booth was the Armour exhibit—endocrine gland and organotherapeutic preparations.

"Ah, my friend, you must hear the story of how some of these products are made," said Dr. Voolayvoo. "It is really wonderful—fascinating. For one pound of their suprarenalin alone, the glands of 135,000 sheep are required." We spent a full half hour there.

A BIG SPHYG

At the Taylor Instrument Companies' Booth we saw a demonstration of their new Office Type Sphygmomanometer. This is an instrument worthy of every physician's attention. Some other very interesting instruments for home use were shown—particularly the Recording Hygrometer and Bath Thermometers in new patterns. Across the aisle we stopped to examine the new (8th) revised edition of Sajous' "Analytic Cyclopaedia of Practical Medicine," shown by F. A. Davis Company. The handsome appearance of this eight-volume set appealed strongly to my guide's aesthetic sensibilities. We also got deeply interested in the new books displayed by this firm, particularly "Regional Anesthesia" by Sherwood-Dunn.

BETTER BELTS FOR BAGGY ABDOMENS

In Spaces 23 and 30 was an exhibit of Abdominal Supports which attracted our attention. This was the well known Spencer line, manufactured by Berger Brothers Company, and included abdominal belts (not corsets) for men and women, abdominal supporting corsets, sacro-iliac corsets and belts, maternity supports, etc. "You will note," said Dr. Voolayvoo, "that these supports are non-elastic and depend on correct design for comfort and efficiency." "Good idea," I thought.

Just then I noticed the Hanovia Chemical & Manufacturing Company's exhibit of the Alpine Sun Lamp and the Kromayer Lamp. I had never seen one of these in action, hence greatly appreciated the actual working demonstration by a competent representative. I found out that these lamps have a wide range of usefulness in applying quartz ultra-violet light for therapeutic purposes.

"Ah, sapsristi, what clear, sharp X-ray negatives," enthused Dr. Voolayvoo, as his eye fell on the Eastman Kodak Company's exhibit, "and made on films, too, which are so convenient, so easy to preserve."

I readily agreed with him and before leaving, jotted down in my note book the words, "Dupli-Tized Films—Eastman."

NICE LITTLE DISPLAY I'VE
GOT FIXED UP HERE: OUGHT
TO STOP MOST OF THEM
I GUESS!

THE X-RAY BEGINS TO PENETRATE

Very smoothly our attention switched to the neighboring exhibit, Spaces 12 and 13, for it was X-Ray machines—the new Kelley-Koett Unit and several other X-Ray specialties shown for the first time. I carried away one of their descriptive booklets. The demonstration of the K. K. Unit, together with those of Eastman negatives, had set up a powerful thinking within me.

Across the aisle was another X-Ray exhibit—The Patterson Screen Company with their Fluoroscopic and Intensifying Screens. Their screens for double screen work have been giving wonderful results, I understand. They had a new catalog on screens and their care. I was glad to get a copy.

MR. FISCHER ENTHUSES

This section seemed to be a veritable X-Ray stronghold. For the very next exhibits to catch our eye were those of the H. G. Fischer & Company and Thompson Plaster Company. I had seen a full page announcement in THE JOURNAL OF THE A. M. A. regarding the Fischer Universal Machine, and that had whetted my desire to see an actual demonstration. Here I saw it and readily understood why it is called "Universal." Mr. Fischer was quite enthusiastic over their new building, too. Said it would enable them to turn out a greater quantity of machines and give better service than ever before. The Thompson Plaster Company had several models, from their portable C up to the big Type F machine which does all kinds of X-Ray work and furnishes

practically every modality that the electrotherapist could desire. The idea of an X-Ray equipment all my own, was indeed growing on me. More catalogs.

"But, come, come, my friend. The time is passing," Dr. Voolayvoo reminded me. "Here is the Becton, Dickinson & Company's exhibit of thermometers, Luer syringes, Yale needles, Ace bandages and Asepto plungerless syringes. And improved, too. Oh, c'est étonnant, how progressive these people are."

WONDER THO IF IT WOULDN'T BE
BETTER TO PUT THE WICKER CHAIR
OVER IN THIS CORNER, AND HAVE
THAT SIGN CROSSWISE, INSTEAD
OF LIKE ALL
THE OTHERS!

Adjacent in Spaces 16 and 17 was a veritable treat for the Eye, Ear, Nose and Throat men—the exhibit of E. B. Meyrowitz Co. Of particular interest were the Braun Snaretome, the Braun Adenotome, a non-luminous Rheostat and a pneumatic Test Type Cabinet with perfect illumination.

WE DO THE BETZ BOOTHS

Next we saw the large and complete display of the Frank S. Betz Company. Previous to that, I had a good catalog acquaintance with the Betz Co., but here were the goods themselves—instruments, apparatus, surgical merchandise, hospital furniture, electrical apparatus—and even a large line of pharmaceutical products. They told me that their line is limited only by the maximum demands of the profession. I believe it, for they seem to have everything a physician needs. Prices reasonable, too.

"See what a splendid set of electrically lighted instruments," said Dr. Voolayvoo, pointing to the Electro-Diagnoset of the American Surgical Specialty Company across the aisle. We watched the demonstration. It is really remarkable the help one can have from these instruments in tonsillectomies and all other official operations or examinations. They can be used in the office, hospital or home.

In the corner space nearby, was the H. A. Metz Laboratories exhibit of Arsphenamine, Neoarsphenamine, Anesthesin, Novocain, Holocain and Pyramidon. This exhibit was of great practical value, because laboratory men were in constant attendance to demonstrate procedures for making solutions of Arsphenamine and Neoarsphenamine.

Going down the aisle, we stopped at Spaces 34, 35 and 36 to visit the Victor Exhibit of X-Ray and Electro Medical apparatus. Again I got to thinking about an equipment all my own. The high quality of materials and fine workmanship evident in the Victor apparatus impressed me very favorably. Just before leaving, Dr. Voolayvoo and myself were rewarded with a pleasant little surprise, especially prepared for Victor visitors. I also asked them to send me a catalog.

BACK, BACK TO BALTIMORE

"Ah, here is the Hynson, Westcott & Dunning exhibit," said my colleague as we started on. "We must see their products, particularly the new germicide Mercurochrome-220 soluble which seems so promising and their Benzyl Benzoate, the non-narcotic antispasmodic." Time was well spent, and I received some valuable information.

"What is this?" I asked, as I saw some steel wafer-like objects lying on a table.

"Those are detachable blades for the Bard-Parker Knife, the safety razor idea applied to the operating knife," said Dr. Voolayvoo. We stopped and the idea seemed so sensible that I ordered a set of the knives and blades, yet wondered why someone hadn't thought of it long ago.

"Do you know," asked Dr. Voolayvoo, "that the Radium Company of Colorado is now producing over one thousand milligrams of radium element per month? Here is their exhibit." The representative showed us various applicators of the latest and most approved types, and explained that the company has recently established service stations in several cities. Time well spent.

In Spaces 27 and 28 was the Squibb Exhibit. It seemed as if they were prepared to furnish any drug, chemical or biologic the physician might need. Their demonstration of the blood clotting powers of Thromboplastin impressed me in particular. "That's something I don't want to forget," said I to my companion, and asked the representative to let me have a sample and descriptive literature.

HORLICK'S THE ORIGINAL

"Ah, here are our old friends, the Horlick's Malted Milk Company," said my colleague as we approached Booths 39

and 40. This exhibit showed "Horlick's Malted Milk" in powder and tablet form; also, Horlick's Food and Horlick's Diastoid. Representatives were busy distributing literature and answering inquiries concerning the various uses of these well known products.

Just then a thought flashed into my mind, and almost convulsively I grasped at my coat pocket.

"What is it, my friend? What is it?" asked my guide somewhat excitedly. "This is it," said I, drawing forth a post card written to my wife on arrival at New Orleans, but still unmailed.

"Ah, that is easily taken care of," said Voolayvoo, "right over here is the Convention post office where your belated missive can be dispatched immediately." That done, we turned to the Oxford University Press exhibit. This had an educational feature in its display of old and rare bibles, religious books and ancient works on medicine. But to me their most interesting and practical features were the famous "Oxford Loose-Leaf Medicine" and the "Oxford Loose-Leaf Surgery." Dozens of standard as well as new works were there, too.

"Sh—sh—", I heard in a nearby booth.

"Ah, that reminds me, we must see De Vilbiss Atomers demonstrated," said Dr. Voolayvoo. "What is an Atomer?" I asked. "An Atomer," answered my colleague, "is a De Vilbiss spray." After seeing these atomizing devices demonstrated, I could readily understand why they merit a name all their own—Atomers.

Next door to the Atomers was Blakiston's book exhibit. I liked the atmosphere and spirit of this exhibit. Their representative made me feel perfectly at home, and I found that we had quite a bit in common. Some of the new books he told me about were quite closely related to my everyday problems.

HOW HEYDEN DOES IT

"Ah, here, my friend, is something 'instructive,'" said Dr. Voolayvoo, as he noticed the Heyden Chemical display of frames showing the products entering into the manufacture of well known medicinal chemicals such as Salicylic acid, Salol, etc. We studied with great interest this part of the exhibit as well as the display of fine chemicals for medicinal and technical use.

Across the aisle was a great showing of instruments by V. Mueller & Co., for general surgery and for specialists

in the different branches such as eye, ear, nose and throat; genito-urinary and obstetrics. Mr. Mueller was giving a most interesting explanation of some new instruments discovered in use abroad on a recent trip by a member of the firm.

Adjoining was another instrument exhibit—that of F. A. Hardy & Company. This was certainly an interesting spot for the Eye, Ear, Nose and Throat surgeons. Mr. Wilhelm, Mr. Frenzel and Mr. Rooney were busy indeed, but not too busy to be courteous.

In the next space we found out some new facts about Mellins Food. As we left, Dr. Voolayvoo said, "How fair and how reasonable are those Mellins people. They present the facts about their preparation and without unduly urging their side of the question, leave the physician to form his own opinion relative to the usefulness of Mellins Food in infant feeding. That is fine, fine indeed."

"But come, we have not yet examined these books in the William Wood & Company exhibit," my conductor said. This proved to be a delightful half hour, for there we found a complete line of medical and surgical books, including the latest works on Medicine, Surgery, Industrial Hygiene, Tropical Medicine, War Repair Work, etc.

Nearby was a demonstration of a little device that interested me keenly—the De Lyte Surgeon. Voolayvoo told me that its manufacturers, the Weder Mfg. Co., had exhibited each year for the last five years and that conventionists always seemed to appreciate greatly the opportunity to see this splendid little contrivance for diagnostic work.

"Do you know Mr. Maltbie?" asked Voolayvoo, as we turned about. "I think not," I answered, and he took me to the Maltbie Company exhibit. Mr. Maltbie was there extending a warm welcome to his old friends, and making lots of new ones. I became much interested in Calcreose

THE A.M.A. PEOPLE CERTAINLY HAVE
THINGS WELL ARRANGED HERE.
BUT THIS LOCATION DOESN'T LOOK
AS GOOD AS ON PAPER, AND THE SPACE
IS FULLY TWO INCHES LONGER THAN
I PAID FOR—
I MUST
SEE
BRAUN.

because it permits a very heavy creosote medication but is free from the characteristic nauseating effects. "I prescribe it wherever creosote is indicated," said my colleague.

DOWN WHERE THE WELCH'S FLOWED

"Ah, mon ami, voila," exclaimed Dr. Voolayvoo, as he looked across the aisle, "here it is at last."

I looked up, and right before us was the Welch Grape Juice Booth, with lots of Welch's on tap. "I will tell the world that that is one fine drink," said Voolayvoo, as he imbibed. "It refreshes us here in full health and strength; think how pleasing it must also be to the sick or convalescent." Grapelade, a pure grape spread, seemed to be another Welch "comer."

"Hello, what have we here?" I asked as my eye fell upon a display of baby clothing.

"That, my friend, is the Vanta line of garments for infants," said Voolayvoo. "You wonder that they are exhibited here? Do you not realize that we medical men can be of great assistance to mothers by showing them the better way to

dress their babies? The Earnshaw Knitting Company have developed unique and original ideas in infant dressing that physicians should know about. With their Vanta garments, the baby is dressed from top to toe without one single pin or button, or once turning him over." Voolayvoo was right. I was glad indeed to have Mr. Earnshaw tell me he would send me a sample Vanta Abdominal Binder.

EMANATIONS OF RADIUM FACTS

Next to this booth was the Radium Chemical Company's exhibit. They were displaying new applicators, screens and other paraphernalia for therapeutic application of radium. But the most interesting thing to me was the fifteen-minute talk I had with a member of the company's technical staff. After all, radium isn't such a mysterious subject, and with the service of this company, its use by physicians is greatly simplified and facilitated.

Occupying Spaces 68, 69, 70 and 71 was the A. S. Aloe Company exhibit. With the liberal terms this firm offers, there really is no reason why any doctor should deny himself the usefulness of any desirable instrument, apparatus or piece of equipment. Aloe will furnish it on easy rental purchase plan.

In the adjoining spaces was another St. Louis exhibitor, the C. V. Mosby Company, with a complete line of medical, surgical and nursing publications. I had already seen a good many new books, but Bartlett's "After Treatment," Hertzler's "Peritoneum," Hazen's "Syphilis," and Warfield's "Arteriosclerosis and Hypertension" were too attractive and interesting to pass up. So we did ourselves full justice by taking plenty of time for the Mosby book exhibit.

IN A TENT, BUT NO SIDE SHOW

"Suppose we step out and smoke a bit," I suggested at this point. "Bonne idée," agreed my guide. Coming back toward the building, we noticed a tent pitched on the lawn. In it was the exhibit of the Abbott Laboratories. We were glad indeed to visit this exhibit. They were showing motion pictures every hour, demonstrating the clinical uses of their Dichloramine-T, Cholesterol-Parresine, the wax dressing for burns, and Parresined Lace Mesh Dressing. After an hour here we stepped back into the exhibit building.

BOONS FOR BABIES

Entering by a different door, we saw the exhibit of the Dry Milk Company in Space 76. "Do you know," said Dr. Voolayvoo, "that dry milk has become quite a factor in the feeding of infants and invalids?" We stopped, examined the preparation and received some very interesting information. A striking demonstration was that showing the curd of dry milk in comparison with that of liquid milk. Sterling Brand Milk Sugar was also on display here.

"And right here," said Voolayvoo, "is Dennon's Food, the whole wheat milk modifier. It has been on the market for about fifteen years now, and has won a well merited place in infant feeding. You must see this exhibit." The Dennon's booth was modest in its decorations, but Dr. Voolayvoo and

I both carried away a neat souvenir gift as we left, and a good impression of the "whole wheat milk modifier."

Turning the corner, we noticed in space number 77 an interesting display of Radium Applicators and Radium Needles by the W. L. Cummings Chemical Company. Special features here were the new and approved radium applicators for treatment of uterine and bladder conditions.

Adjoining this booth was an exhibit of the Dr. Beachler Standard Sphygmomanometer by the Reliable and Efficient Mfg. Co. This is a mercurial instrument and is so simple, so easy to operate, and is so convenient that I ordered one. It is small and compact enough to carry in one's pocket or bag.

WHERE DOCTORS MEET DOCTORS

"By the way, are you familiar with the Calco pharmaceutical products?" asked Voolayvoo. "This company has been very well received by the profession." Drs. F. Elbert Davis, B. A. Oliver and J. H. Seibert were in charge, and we listened with interest to the facts they presented about Cinchophen, Albutannin, Acetannin, Chloramine, Dichloramine-T, and other Calco products.

Halting me at the Marshalltown Laboratories booth, Dr. Voolayvoo exclaimed, "Ah, here is something fine—a transparent, flexible, waterproof tissue that will not adhere to a wound." I took down the name "Cellosilk" and noted, too, that it comes in an impervious form, and in a perforated form for dressing wounds requiring air and drainage.

FIRST AID FOR THE NEO-NATI

"Say, here is something we must not pass up," said I as I glimpsed a Lungmotor demonstration. We stayed here for some time, and I found out, somewhat to my surprise, that over 6,000 Lungmotors are now in service in hospitals, municipalities, and industrial plants. "Voila la petite," exclaimed Voolayvoo, pointing to the New-Born Infant Lungmotor. "That is a device that every obstetrician should have as a necessary part of his equipment," he added. I remembered a bad case of asphyxia-neonatorum that I had recently had, and lest I should forget, took with me a descriptive circular.

Next, we stopped at the booth of the Foregger Company, and saw a demonstration of the No. 66 "Gwathmey" anesthesia outfit. They were showing some of the very latest developments in anesthesia appliances and our time here was well spent.

Over at the Buzzell-Flanders Company booth, we found out some new things about sutures and ligatures. For years this firm has prepared all of Dr. Henry O. Marcy's Kangaroo Tendon under his direct supervision, and I was glad indeed to see this tendon and have its advantages told me. They are also headquarters for surgeons' needles and hypodermic needles. I'm going to keep them in mind.

THE X-RAY IDEA PENETRATES DEEPER

At the Southworth Company's exhibit, my mind again reverted to the thought of an X-Ray machine all my own, for here were some authoritative and practical books on roentgenology, "X-Ray Examination of the Alimentary Tract," by Dr. James T. Case; and "X-Ray Examination of the Chest for Pulmonary Tuberculosis," by Dr. Kennon Dunham. A number of other helpful and instructive books were displayed, among them being "Pediatrics" by Dunn, and "Rational Therapy" by Lerch.

MEETING THE SOUTHERN EXHIBITORS

"Now let us step in here and see a real New Orleans Exhibit," said Voolayvoo. He pointed out the booth of the McDermott Surgical Instrument Co. Being at home, this firm was able to have one of the most complete exhibits at the meeting. There were surgical instruments, the most modern makes of operating tables, hospital furniture and also specialties such as the Cave-McDermott Ether Outfits, Lynch Suspension Outfits and Matas Jaw Splints. A full force of representatives were on hand, and with characteristic Southern courtesy and hospitality took great pains to see that we got the most out of their exhibit.

Down the aisle, in Booth 107, we came across another interesting exhibit of surgical instruments. This was by Lawrence Everhart of Atlanta, Ga. His Paquelin Cautery and American made Killman Dilator seemed to be very popu-

lar, and well they might be, for he was selling them at the popular price of \$35.00 each.

"I take it that you are interested in matters pertaining to hospital work, yes? Then we must step back here to Space 86 and talk with Mr. Crain of 'Hospital Management,'" said my guide. The suggestion was good, and we found the Crain Publishing Company were performing a real service to Conventionists by showing them how to keep better posted on hospital matters. I was presented with a copy of the April issue of "Hospital Management," and found it so good that I subscribed for a year before leaving.

TO KEEP AMERICANS DRY

"Sapristi, what is the gentleman doing?" exclaimed my friend Voolayvoo, pointing to the booth of the Waterproof Fabric Company. We stopped and watched. Here was a

YES, DOCTOR, (HOLY SMOKES WHAT A CROWD!) THIS IS OUR LATEST MODEL! (I DIDN'T THINK THEY'D SWAMP ME LIKE THIS)—JUST LEAVE

pan of water boiling. Sagging into it was a piece of thin, white fabric. The gentleman struck a match, laid it burning on the fabric, and much to our surprise, it continued to burn quite undisturbed by the boiling water beneath. The fabric is called Sani-Dri, and I found out that surgeons' aprons made of it are available.

Adjoining this booth was the Pulvula Chemical Company's exhibit. This was very attractive and the unique demonstrations were commanding the interest and attention of many of my colleagues. No wonder, the

way those medicated powder ointments resist moisture was indeed convincing. Before leaving, I jotted down in my note book "Dolomol Dry Dressing" and "Pulvula Powder."

Just at the doorway to the next room, we found the exhibit of D. Appleton & Company. They were showing the new medical books of this season and last year as well as new revisions of many of the standard editions now famous throughout the world. A novel and interesting feature of their display was an historical exhibit presenting manuscripts, rare first editions, autographed letters, etc. Really, it does one good to get into the spirit of these great publishing houses by learning something of their history.

THAT LOOSE-LEAF IDEA AGAIN

"Ah, here is the Nelson Loose-Leaf Medicine," said my guide, as we stepped into the next room, "a complete system of Living Medicine by Leading Medical Authorities of the world." A representative showed us in a very interesting way the service this system gives the doctor, and how it is kept continually up-to-date by the loose leaf device, and supplemented by abstracts, special articles and by the services of the Research Bureau. I liked it very much.

In the next booth, Space Number 98, the Takamine Laboratory representatives were exhibiting Arsaminol and Neoarsaminol. I was greatly impressed with the great care taken in testing these products. According to regulations, they are tested at the Takamine Laboratories and by the U. S. Public Health Service, and "to make assurance doubly sure", each lot is tested clinically by a recognized authority.

In the next booth were "Anatomik" shoes, displayed in a number of different styles. There were specialties particularly suited to the requirements of the Southern trade. The manufacturers have been very successful in producing "attractive" footwear for prevention and relief of foot troubles. "They have, as it were, sugar coated the pill of wearing orthopedic footwear," commented Dr. Voolayvoo, as we turned to the exhibit of E. Leitz, Inc. Here was a variety of fine apparatus now of Leitz manufacture, but formerly imported. Voolayvoo called my attention especially to the new "Elei" Colorimeter, a modified Duboscq.

THE BOOTH BLANCHE

"Ah, how beautiful, how appropriate," exclaimed Dr. Voolayvoo, as he noticed the Mead Johnson & Company booth—all pure white, decorations, tables, chairs and everything. It seemed particularly fit as a setting for the display of their infant diet materials, which are now so well known by members of the profession. I'm glad I visited the 'white booth.'

"Now," said my guide, "we have not much more time." It was true. For in addition to the exhibits already mentioned we had tarried at the booths of the Boehm Surgical Instrument Co.; had looked over the X-Ray supplies of the George W. Brady Co.; had seen a demonstration of one of the Campbell X-Ray Units; had examined the tissue dressings and bandages of the Dennison Mfg. Co.; had talked with a General Electric representative about their new X-Ray tube; had seen the Jaekh Mfg. Co. compressed air cabinets and the Sanborn Blood Pressure Outfits demonstrated; had purchased some iridio-platinum needles from Mr. Wilson of Wilson & Wilson; had looked over the Practical Medical Series of the Year Book Publishers; and had carefully studied the anatomy and physiology of a Sealy mattress. And every exhibit had netted us some new ideas.

"Yes it has been one big day," said Voolayvoo, "but we must see the Sorensen Exhibit here in Spaces 102-103." Representatives were showing the different models of Sorensen Tankless Air Compressors. "Are they not a great improvement and convenience?" asked my friend. "Indeed so," I replied and asked the representative to send me literature. Another interesting feature here was a Specialist's chair, this being its first appearance on the market.

MEASURED ANESTHESIA—WHY NOT?

"Here, too, my friend, you must see the famous Connell Gas Oxygen Apparatus—the machine with the meters," said Voolayvoo, pointing to the Scientific Apparatus Company booth. "Meters," I said, "good idea, charge 'em so much per thousand."

"Ah, no, my friend, you are facetious," rejoined Dr. Voolayvoo, "and this is a serious matter. We measure with great exactitude our dosages of liquids, solids or powders—why not of Nitrous Oxide, Oxygen or Ether?" After seeing the machine demonstrated and noting the ease with which one may keep tab on the amount of gas being delivered, I felt like apologizing to my good colleague for my facetious remark. He was looking at his watch.

THOROLY CONVINCED BY "THORO"

"Just one thing before we go," he said, "over here is a treat I have reserved for you until the last." He led me to the exhibit of the Thoro Corporation. I understood. This was Thoro—the new, hygienic skin cleanser that I knew so many physicians, dentists and other particular people are now using. "See the handsome white enamel holder, and here is the powder itself," said Voolayvoo, "so pure and cleanly." In the adjoining washroom I had my first "Thoro" washup, but not my last, I assure you. For on the way out, I ordered two Thoro Holders, and a supply of Thoro Powder for my office and home.

We started toward the elevator. A great crowd was there. I heard the bell ringing at regular intervals, buzz—buzz—buzz, it continued on and on. I thought it strange to ring an elevator bell like that, I became confused. Someone punched me in the ribs—then another punch—and all the time that confounded bell buzzing—I felt strange—"Voolayvoo, Voolayvoo, where are you," I called—another unmerciful punch in the ribs and I jumped violently.

"—for heaven's sake," a familiar feminine voice was saying, "why don't you go down and answer that midnight call? That phone's been ringing for the last five minutes."

"Yes, my dear," I answered, composing my variegated emotions as best I could, "it's surely 'fierce' to be called out like this, but after all, being a doctor has some compensations, at least."

The End of a Perfect Day.

The above dream is guaranteed to be correct in its details, if advance information regarding the New Orleans exhibits is to be depended on. Not all firms were able to supply such information, but it can be taken for granted that every exhibit will be worthy of the conventionist's close and careful study.

LETHARGIC ENCEPHALITIS

HISTORY, PATHOLOGIC AND CLINICAL FEATURES, AND
EPIDEMIOLOGY IN BRIEF *

SIMON FLEXNER, M.D.

NEW YORK

It is of more than ordinary interest that within the last dozen years at least two epidemic diseases, affecting chiefly the central nervous system, have prevailed widely in Europe and America. The first is poliomyelitis, which since 1907 has passed through several phases in the United States and culminated in the outbreak of unparalleled severity, centering in New York State, in 1916. The second is lethargic encephalitis, apparently only recently introduced in and already widely distributed through this country. It is highly desirable that the main facts known about the latter disease should be given publicity; and it may well be that the experience, often of tragic nature, gained with poliomyelitis, may serve us in dealing more effectively with the encephalitis peril. Hence, by way of introduction, I shall sketch the recent history of poliomyelitis.

POLIOMYELITIS

The occurrence of poliomyelitis in America and generally in Europe beginning in 1907 followed, it now appears, the severe epidemics of Norway and Sweden, which reached a first climax in 1905. Indeed, poliomyelitis became so widespread after 1905 that it may be regarded as having become pandemic. Besides Europe and the United States, South America, Australasia and the far eastern countries all were involved. Poliomyelitis, it is true, had been mildly epidemic in the United States before 1907; but the most severe of the earlier outbreaks were inconspicuous as compared with the later ones, both as regards the number of persons affected and the territory invaded. Thus, the severe Vermont epidemic of 1894 included 130 cases; and it is worth noting that no extension into distant territory followed in its wake.

It is customary to ascribe to Wickman, who studied the Swedish epidemic of 1905, and gave to the world in 1907 his remarkable book on epidemic poliomyelitis,¹ the first account of the so-called abortive cases of poliomyelitis. But Caverly, who studied the Vermont outbreak,² clearly described cases which did not go on to frank paralysis, but terminated in prompt recovery after symptoms which seemed to presage the onset of paralysis. As these "imperfect" or nonparalytic

instances arose along with the frankly paralytic cases, it seemed to Caverly that they belonged in the same category with the latter. This conception is now abundantly justified. And it is due to Wickman that the abortive type of cases of epidemic poliomyelitis is so widely recognized. The epidemiologic significance of the abortive cases is considerable, since many are ambulatory and most are invalidated for a few days at most; they thus furnish a ready means of distributing freely the inciting microbic agent or virus of poliomyelitis in their surroundings. From the public health point of view, the abortive and ambulatory cases of poliomyelitis are more dangerous than the frankly paralytic, since by the very nature of the circumstances the latter are restricted in their contact with healthy persons.

We may think that the forerunners of these epidemics of poliomyelitis were imported into the United States about 1906 or 1907; that the cases of the disease or carriers of the virus first had merely local distribution, but that gradually the conditions favoring a wider spread of the disease became more extensively developed; that thus the more numerous and severer outbreaks arose; until finally, conditions in certain localities having become highly favorable, the terrific explosion with its thousands of paralyzed patients occurred in 1916, since which time the disease, while still present, has reverted to a relatively quiescent state.

The medical profession in general in the United States in 1907 was not informed and ready to deal with the epidemic of poliomyelitis. Practically none of the profession had had previous experience with the disease except in its rare sporadic form, which at first seemed improbably connected etiologically with the epidemic affection. Few physicians knew of the succession of outbreaks, small and large, that for many years had been going on in Norway and Sweden. When, therefore, the epidemic appeared in the United States, there was inevitable confusion of diagnosis, lack of understanding of the infectious nature of the disease and the degree of its communicability, uncertainty as to the public health policy to be pursued, and, finally, in places an undue harshness in the endeavor to curtail its ravages.

Gradually a deeper knowledge of the disease by the profession at large has removed many of these disabilities, and a wider understanding of its atypical forms is rendering feasible the early and more complete institution of those protective public health measures with which hope of better control of epidemics is inseparably connected.

LETHARGIC ENCEPHALITIS—HISTORICAL

With this introduction, I shall now consider certain historical points regarding lethargic encephalitis. It

appears that the first cases of that disease recognized in the United States occurred in the winter of 1918-1919. In contradistinction to epidemic poliomyelitis, there is no reason to suppose that this epidemic affection of the central nervous system ever before existed in America. This point is an important one. At present the disease seems to be widely distributed, as cases have been reported from many states.

It is possible to trace the cases of lethargic, or epidemic encephalitis, now arising in this country, to an outbreak which occurred in Vienna and neighboring parts of Austria in the winter of 1916.³ Because of war conditions, knowledge of this unusual disease did not at once reach western Europe and the United States; but nevertheless cases of the disease occurred in England and France in the early months of 1918, and in America about one year later.

Both in Austria and in England, in which countries the first cases were observed, respectively, in eastern and western Europe, the disease was first mistakenly attributed to food intoxications. In Austria the early cases were ascribed to sausage poisoning, in England to botulism arising from various foods.⁴

This error is not perhaps as remarkable as might at first sight appear. In the first place, both countries were laboring under unprecedented conditions of food shortage, Austria because of the blockade, England because of the submarine. Moreover, because of this shortage, preserved foods were employed on a scale never before equaled, and, of course, waste and refuse were reduced to a minimum. Furthermore, an early symptom of this encephalitis is third nerve paralysis—giving rise to diplopia, ptosis, etc.—which happens also to be an early symptom in certain forms of food poisoning and notably in botulism.

Ultimately, in both countries the notion of food origin became untenable, and the disease was recognized as arising independently of diet and other usual conditions of life, and came to be viewed as probably of microbic origin and of communicable nature.

PATHOLOGIC

The first fatal cases, which occurred in Vienna, supplied on histologic study a physical basis for the symptoms observed during life; and the first English and French cases similarly examined microscopically showed lesions identical with those described for the Austrian cases. In due time the anatomic study of cases arising in the United States and still other countries showed close agreement with the others, and now a histologic basis of the pathology of the disease, of remarkable concordance, has been provided. On this basis we may now regard lethargic encephalitis as representing a definite pathologic as well as clinical complex, and to consider it as a distinct disease.

The histologic changes or lesions of lethargic encephalitis may be both extensive and profound. Those so far described as confined to the central nervous system affect particularly the brain and especially the gray matter at the base of that organ. While, indeed, any part of the gray matter may be involved, and lesions are found in the cortex and in the cerebellum, the structures particularly affected are those about the third ventricle, the aqueduct of Sylvius, the lateral ventricle and optic thalamus, and the pons and medulla. The spinal cord is variably involved. In

general, it may be stated that the severity of the cerebral lesions diminishes from before backward; the upper or cervical cord often shows changes; but it is still to be determined how often and to what extent the cord as a whole is affected.

The lesions themselves consist of cellular aggregations about the blood vessels, cellular infiltrations in the nerve tissues themselves, small, often microscopic hemorrhages, and an outpouring of plasma or lymph into the tissue interstices (edema). The cellular accumulations and invasions are chiefly mononuclear in nature (lymphocytes, plasma cells, polyblasts); polymorphonuclear cells are also encountered, but are relatively inconspicuous. The lesions themselves occur in nodular and in diffuse forms; and those of the tissues are at times clearly associated with the vascular affections and at other times are so extensive as not to be brought into relation with particular vascular involvements. The paralyses of the ocular, facial and other muscles which sometimes occur arise, with rare exceptions, from the cellular and other invasions of the nuclei of the corresponding nerves.

CLINICAL

The clinical phenomena or symptoms of lethargic encephalitis are referable to the lesions of the central nervous organs or the pathologic process, as sketched. It is perhaps too early in the study of the disease to set up hard and fast clinical varieties or types. However, attempts at classification have already been made. One of the most comprehensive is that of MacNalty,⁵ which is reproduced here, as it is suggestive and may prove useful in practice. MacNalty distinguishes six groups of cases: (1) cases with general symptoms and without localizing signs; (2) cases with third nerve paralysis and general disturbance in the function of the central nervous system; (3) cases with facial paralysis and general disturbance in the function of the central nervous system; (4) cases with spinal manifestations and general disturbance in the function of the central nervous system; (5) cases with polyneuritic manifestations and general disturbance in the function of the central nervous system, and (6) cases with mild or transient manifestations (so-called "abortive" cases). To these should be added cases of paralysis of other motor cranial nerves than the third and fifth, such as those of deglutition and respiration.

Probably there is an incubation and prodromal period which precedes the onset of the striking subjective and objective symptoms of the disease; but thus far these have not been defined. Hence the so-called onset of the disease is usually described as sudden or acute. The latter is, indeed, so striking that the patient is able often to tell the precise hour of a particular day on which he fell ill. Actually the striking symptoms often develop more slowly than in poliomyelitis.

The initial symptoms are described as chills, lassitude and general malaise, headache and general pains, nausea and anorexia, associated often with the common symptoms of upper respiratory catarrhal affections. Fever is an irregular manifestation. It may be present at onset or may appear only later. The temperature range tends not to be high—from 101 to 102—but it sometimes swings to 103 or 104. As the symptoms develop there arise lethargy or drowsiness, vertigo, tinnitus, muscular weakness, blurred or misty vision, diplopia, photophobia, tremors and twitlings, ataxia, delirium, irritability, restlessness, mental depression and other

3. Von Economo, C.: Die Encephalitis Lethargica, Vienna, 1918.

5. MacNalty, A. S. (Footnote 4) p. 12.

alterations, difficulty in articulation and in swallowing, stiffness of neck and spasticity of other muscles, sweating, hiccup, etc. Among the earliest symptoms to arrest the attention of the patient and the physician are diplopia and ptosis with varying degrees of lethargy. But still other paralyses (e. g., facial) may appear, and the lethargy may arise independently of all localizing nervous signs.

The outstanding feature of the disease is the lethargy, which is progressive in character and present in the great majority of cases (80 per cent.?). It may appear suddenly, but usually is gradual in onset. The patient becomes apathetic and dull, appears dazed or stupid, the hours of sleep become prolonged, and he is hard to wake in the morning. Moreover, he may fall asleep at odd hours—while engaged at work or at mealtime. The lethargy may deepen into stupor or even into coma. Its duration is variable—a week, a month or even longer—up to four months. Even after long periods, recovery may still follow. During the lethargy, there may be lack of facial expression (masklike features). The usual state is one suggesting profound sleep, from which the patient can be aroused by loud speaking, prodding, etc., to partake of food or answer questions. But cases in which marked restlessness and even mania have been present followed by lethargy have been noted.

Symptoms referable to irritations of the meninges appear. Usually they are slight, and while sometimes arousing suspicion of acute meningitis, that condition is excluded by lumbar puncture and examination of the cerebrospinal fluid. The fluid tends to be under somewhat increased pressure, but clear. The number of cells is slightly increased (very rarely 100 per cubic millimeter), and the globulin content little and sometimes not at all excessive. The cells, which range usually around 10 to 20 per cubic millimeter, consist partly of mononuclear and partly of polymorphonuclear leukocytes. In addition, the important point of the rare presence of Kernig's sign should be mentioned.

The occurrence of paralyses of the face muscles has been mentioned. Paralysis of the extremities is rare: wrist drop has been noted in at least one instance. But a far more common symptom is rigidity or spasticity, chiefly of the extremities, which in a few cases has been observed to extend to the spinal and even the facial muscles, making a picture suggestive of paralysis agitans. This spasticity of the extremities is ascribable to involvement in the encephalitic process of the lenticular nucleus and the corpus striatum.

The duration of the stupor is very variable; it may last a few days, for weeks or even for months, and recovery still take place. The return to clear mentality is usually gradual; muscular power also tends to return slowly, and general convalescence tends to be prolonged. In paralytic examples of the disease, rapid, complete or partial clearing of the palsies has been noted.

The number of cases of undoubted lethargic encephalitis thus far reported is too small to indicate the age periods of greatest incidence. For the present it may be stated that the disease occurs at all ages, namely, from a few months to advanced years (over 70 years). Likewise, it appears as if the two sexes were about equally attacked.

The fatalities reported range from 20 to 35 or 40 per cent. Probably the higher mortalities refer to groups of the severer cases of the disease. Since knowledge of the disease is still very restricted and

diagnosis still in its beginnings, probably many cases of lighter affection are overlooked or given other names and interpretations, thus making it impossible at present to arrive at an accurate estimation of the prognosis and mortality. At best, however, the disease is to be regarded as serious, whether from the point of view of long duration from onset to restoration to health, or of fatality. The chief immediate causes of death reported have been intercurrent pneumonia and paralysis of the respiratory center in the medulla.

Present indications are that the degree of communicability of lethargic encephalitis or susceptibility to the disease is low, possibly equaling that of epidemic poliomyelitis as observed in ordinary times. The seasonal incidence seems to be midwinter, in that respect resembling epidemic meningitis and differing widely from epidemic poliomyelitis, which prevails usually in midsummer and early autumn.

Explanations of the lethargic state have been offered. A toxic origin is, of course, possible. It seems more likely, however, in view of the nature and distribution of the lesions, that its source is rather a mechanical one. It is known that the sensory stimuli from the special and other senses pass by way of the thalamus to the cerebral cortex.⁶ Since, therefore, the thalamus is so commonly the seat of the cellular infiltrative lesions described, it would appear that the stimuli are interrupted in that organ on the way to the cortex, whence a kind of sleep supervenes. The obstruction to the stimuli is not absolute, since the patient can be aroused by increasing their intensity (as by loud speaking, prodding, etc.)

EPIDEMIOLOGIC

It is now sufficiently obvious why the popular name of "sleeping sickness" has been applied to this malady. The disease is, of course, wholly distinct from African sleeping sickness, which is a trypanosomal infection carried from person to person by means of an insect vector—the tsetse fly.

When an apparently new disease arises, it is always important to inquire whether the particular set of symptoms that are taken to characterize it has been observed and recorded before.

In the present instance there are two significant records which may easily refer to a similar and possibly identical disease. The first one dates from 1712 and refers to an outbreak of so-called sleeping sickness centering about Tübingen in Germany. The second record dates from 1890 and deals with a rather puzzling malady called *nona*, which is described rather in the lay than the medical literature of the time and seems to have prevailed in the territory bounded by Austria, Italy and Switzerland. In respect to neither instance, however, do the records contain the minuter data which would admit of a certain identification of the disease described with the encephalitic malady we are considering.

One circumstance is, however, significantly suggestive. The location of the 1890 affection "*nona*,"⁷ which was characterized by somnolence, stupor and coma, coincides roughly at least with that of the first cases reported in the present epidemic. The question may, therefore, well be raised whether the endemic home of this epidemic variety of encephalitis may not be that corner of southeastern Europe overlapping the three countries mentioned. If this should prove to be prob-

6. Head, H., and Holmes, G.: *Brain* 34: 102, 1911-1912.

7. The etymology of this term is not known. It has been suggested that it is merely a corruption of the term "coma."

able, the next questions to arise would relate to the circumstances under which the disease slumbered on in ordinary times, and to the conditions that favored a greater activity and a wider spread about the year 1916.

To deal with the first one will require particular and intensive studies carried out with the especial object in view to disclose hidden cases in the region originally affected. An answer can in the meantime be hazarded to the second question. The depressing effects of war, acting by way of hunger, cold, migrations of populations, and general insanitation, might initiate the conditions through which a low endemic might well be converted into a higher epidemic incidence of the disease.

In effect, a similar set of depressing and favoring conditions may be supplied by a highly debilitating and destructive epidemic, such as the periodic waves of pandemic influenza which recur from time to time. In this manner may possibly be explained the coincidence of the Tübingen epidemic of 1712, also called sleeping sickness, and of the "nona" of 1890 with epidemic influenza, just as the wider distribution of the encephalitic malady and the influenza epidemics of 1918 and of 1920 may be similarly associated. In other words, what the depressing circumstances of the war did for Austria-Hungary in 1916, the pandemic of influenza may have done for the rest of the world in 1918 and subsequently, namely, prepare the soil, as it were, for the growth in number of cases and for increase in intensity and capacity for spread of an infectious nervous disease ordinarily narrowly localized and moderately benign.

This relationship of lethargic encephalitis to the epidemic of influenza has, indeed, led to a discussion as to whether the former is not merely a sequel—early or late—attending a certain, if only small number, of cases of epidemic influenza.

Regarded merely chronologically, the question thus presents itself: In 1916, when the first cases of encephalitis appeared or at least were recognized in Austria, the epidemic of influenza which prevailed later, in 1918, had not yet been noted. In the instances of England, France, the United States and some other countries, the epidemic influenza and cases of lethargic encephalitis were more or less coincidental. Since influenza varies so much in degree of severity, it is of little moment to debate whether or not victims of the encephalitis had previously suffered from influenza.

On the other hand, there is no recognized numerical relationship between the extent of influenza and the number of cases arising, or at least identified, of the encephalitis. It is, of course, true that encephalitis has long been recognized as one of the sequels of epidemic influenza. Indeed, in the etiology of encephalitis, influenza occupies a prominent place; but in no other pandemic of influenza has this remarkable association of encephalitis occurred with certainty. Little weight can be given the supposed coincidence of influenza and the "sleeping sickness" of 1712; and it is highly improbable that the semimysterious affection, "nona," which dates from 1890, should have taken its origin from the influenza epidemic in southeastern Europe at that period and the association not have been observed elsewhere in Europe or even in America at the same time as a concomitant of the influenza epidemic, which raged with great intensity in those countries. Moreover, the occasional cases of encephalitis definitely observed to follow attacks of influenza have presented a more hemorrhagic character, and some-

times have been attended by Pfeiffer bacilli in the nervous tissues and meninges, which is not the case in the lethargic disease we are now considering.

Finally, should the reported experimental transmission of the encephalitis to animals be confirmed, a further distinction from the influenzal variety will have been established. Therefore, the outbreak of lethargic encephalitis either antedated (Austria) the pandemic of influenza of 1918, or (in other countries) the two diseases more or less overlapped, that is, although probably quite by accident, they prevailed concurrently. It is desirable, for the time being at least, to regard them as independent diseases.

The history of lethargic encephalitis indicates its infectious and also its communicable nature, but thus far single rather than multiple cases have been observed in family and other intimate groups of persons. However, two cases in a family have very rarely been noted; and in one instance an institutional outbreak has been reported in which among twenty-one inmates of a girls' home twelve cases arose, with five deaths.⁸ Whether more accurate means of diagnosis, through which the nonlocalizing or "abortive" and the frankly paralytic lethargic cases would be more certainly associated and thus lead to a general revision of present views regarding multiple cases, can only be surmised. Obviously, in the interest of knowledge as well as of the prevention of the disease, close attention to this point is desirable.

It is now a matter of great importance to determine the precise nature or etiology of lethargic encephalitis. Many unsuccessful attempts have been made to communicate the disease to monkeys and other animals through the inoculation of nervous tissues showing the particular lesions, in the manner so readily and successfully employed in monkeys for poliomyelitis. This circumstance alone would serve to distinguish this epidemic encephalitis from epidemic poliomyelitis. But in two or three instances, what are stated to be successful transmissions of the disease to animals have been reported.

Von Wiesner⁹ of Vienna inoculated a monkey subdurally with nervous tissue from a fatal case of von Economo's. This animal quickly became severely sick and died in about forty-eight hours. At necropsy a meningo-encephalitis was found, and from the lesions a diplostreptococcus was cultivated. While von Wiesner regarded this experiment as successful, further investigation has indicated that the infection with the bacteria was an accidental and secondary process, and the diplostreptococcus is not etiologically related to lethargic encephalitis.

Loewe, Hirshfeld and Strauss¹⁰ inoculated rabbits and monkeys with filtered extracts of the nasopharynx of cases of the encephalitis and, also, with filtered nasopharyngeal washings, and have induced a meningo-encephalitis in those animals. Apparently they did not succeed in infecting those animals by inoculating the affected nerve tissues themselves. They also believe that they have cultivated a minute organism, resembling the globoid bodies of poliomyelitis, which they think may be the inciting microbic agent of the disease. Discrepancies exist between the positive results of these authors and the many failures of others with similar inoculations which only greater experience can clear up.

10. Loewe, Leo; Hirshfeld, Samuel, and Strauss, Israel: J. Infect. Dis. 25: 377 (Nov.) 1919.

Finally, McIntosh,⁸ of the London Hospital, announced that a monkey inoculated with the material from the fatal cases in the home for girls, already referred to, presented lethargic symptoms and tremors and died. The brain on examination is said to have shown lesions similar to those found in human cases of lethargic encephalitis.

CONCLUSION

The foregoing account represents, in brief, the present state of our knowledge of the interesting and important disease—lethargic or epidemic encephalitis. Obviously, that knowledge is still very imperfect. It is still too soon to say whether or not we are now at the threshold of the clearing up, by way of animal experiment, of the etiology and mode of communication of this menacing disease, as was accomplished so recently, and also by animal experiment, in the case of poliomyelitis. It is to be sincerely hoped that we are. But at this moment, and while waiting for the ultimate and convincing experimental results, one need entertain no doubt of the infectious and communicable nature of lethargic encephalitis.

The belief that lethargic encephalitis is a communicable disease imposes certain responsibilities on the medical profession to limit its spread. The outstanding obligation is perhaps the close study of suspected cases in order to determine their real nature, meanwhile holding them under such conditions of isolation as is usual with this class of diseases. Then every effort should be made to determine the existence of, and to detect and control the ambulant or abortive cases, having in mind that they may be more significant than the frankly lethargic and paralytic ones from the public health point of view. Since the nasopharyngeal secretions have become suspected of harboring the inciting microbic agent, adequate measures of controlling the distribution of those secretions into the surroundings of patients should be carried out. It is self-evident that the physician should invite the cooperation of pathologist and bacteriologist in attacking the unsolved problems presented by this unusual disease. It is to be hoped, indeed, that the disease may not secure a permanent lodgment in the country; on a wider knowledge of its occurrence and a deeper understanding of its nature, which the studies of the immediate future may yield, much, therefore, may depend.

CHYLOUS ASCITES DUE TO CARCINOMA OF THE STOMACH

H. V. HENDRICKS, M.D.

Assistant Physician, Traverse City State Hospital

TRAVERSE CITY, MICH.

The case here described is considered interesting enough to deserve a brief report.

REPORT OF CASE

History.—B. J. B., white man, farmer, with a negative family history in regard to malignant disease as far as known, with a brother, however, who was insane and a father who was alcoholic, had had measles, mumps and whooping cough early in life, had used alcohol to some extent, and at 16 years of age had suffered from insolation and had been called "queer" afterward. At 42 he had been kicked in the forehead by a colt, after which his peculiarities had gradually become more pronounced until he finally became more or less violent and, Oct. 28, 1907, at the age of 64, was committed as insane to the Traverse City State Hospital. His condition was regarded as a case of dementia praecox of many years' standing.

Physical Examination.—This was essentially negative except for a few hyaline casts in the urine and slight thickening of the radial arteries.

Clinical Course.—In July, 1915, it was observed that the patient, then 72 years of age, was becoming pale and thin, and that his skin was becoming slightly yellow. August 5, the urine showed a trace of glucose and a few casts; the left pupil was greater than the right and reacted to

light better than the right. The knee jerks were very active and equal. August 6, examination of the blood revealed 65 per cent. hemoglobin and 2,912,000 red cells per cubic millimeter which showed a certain amount of variation in size and shape. August 20, after the patient had been kept in bed and given liquor potassii arsenitis (Fowler's solution), the hemoglobin had increased to 80 per cent. and the red cells to 3,832,000.

In September, the patient began to have trouble with his stomach; he vomited more or less, and at times had difficulty in retaining solid food. The improvement under Fowler's solution did not persist, so its use was discontinued. September 28, examination of the heart was negative; the pulse was 118 and of fair tension. On percussion, the lungs showed dullness. Fine crackling râles were heard in the right supraclavicular space, and there were scattered squeaking râles in the lungs. October 14, the blood showed 60 per cent. hemoglobin and 4,800,000 red cells; and the blood smear showed 82 per cent. of polymorphonuclears, 16 per cent. mononuclears,

Fig. 1.—Section of stomach under high power: mass of cancer cells infiltrating muscular layers. Photomicrograph by Dr. W. P. Stowe.

1 per cent. eosinophils and 1 per cent. mast cells. There was still considerable variation in the size of the red cells. By December 3, the patient had become more emaciated and still had a yellowish hue. Examination of the chest then revealed a few râles in the apexes and diminished resonance at the right apex. On the left side of the neck just above the clavicular space, five or six firm, nontender glands could be felt and seen; the inguinal glands seemed prominent, probably on account of emaciation. The patient grew progressively worse, continued to have trouble with his stomach, and retained nourishment poorly. No blood was ever observed in the vomitus or in the stools, which were always a normal color. Jan. 24, 1916, there was slight dulness at the base of the right lung with a few scattered râles there. The legs and thighs were tender; the left leg was somewhat edematous. At that time, the blood showed 25 per cent. hemoglobin and 3,116,000 red cells; white count revealed 6,700 cells, with 57 per cent. of polymorphonuclears; the red cells were somewhat irregular in shape, but no nucleated red cells were found. The skin became a deeper yellow after this, and a slight puffiness appeared around the eyes. The patient died, Feb. 9, 1916.

Necropsy Findings.—

Two and one-half hours after the death of the patient, Dr. F. C. Mayne and I performed the necropsy. The body was slightly built and showed marked emaciation. The thorax was slightly emphysematous and the abdomen was somewhat distended. There was a small trophic ulcer over the right trochanter and another over the sacrum. The skin was slightly atrophic and yellowish brown. The superficial veins of the abdomen were dilated, more so on the left than on the right. The muscles were small and atrophic. There was only a slight amount of rigor mortis. There was a slight amount of edema in the lower extremities, especially in the left.

The abdominal cavity contained no free gas, but it did contain a milky fluid, evidently chyle. This was not measured, but was estimated to be several hundred cubic centimeters. The stomach was large and distended with a large amount of fluid contents. A small, hard mass could be felt at the pylorus. There were adhesions extending from the gallbladder to the duodenum. The omentum was normal, containing very little fat. The intestine was normal in outside appearance and to palpation. At the pyloric end of the stomach, just inside the sphincter, there was a thickening of the stomach wall over an area about 3 cm. in diameter with a depression in the center and a raised hypertrophic border. The head of the pancreas seemed larger and harder than normal. The liver was rather small, and did not extend down to the costal margin. Scattered over its surface were several raised yellow areas ranging from 2 to 20 mm. in diameter. On section the inside of the liver showed these areas also. At the hilum were a number of enlarged lymph

glands. The mesentery contained only a little fat, but when it was cut, a milky fluid like that in the peritoneal cavity oozed out from dilated lymphatics. There were many enlarged mesenteric lymph glands, especially in the upper part of the abdomen. The kidneys and suprarenals were not especially remarkable in gross appearance. The spleen was about one-third the normal size, hard and lobulated and rather grayish-brown. The appendix was small and slightly adherent to the cecum.

The thorax contained a few hundred cubic centimeters of clear yellowish fluid in the pleural cavities. The thymus was absent. The pericardium was normal, and there was no excess of pericardial fluid. The heart was small and flabby. The heart valves appeared normal. The heart muscle was yellowish red. The right lung was strongly adherent at the apex and side and in the back. There were adhesions at the apex and at the base and front of the left lung. The latter adhesions were so dense that it was necessary to cut them. There were numerous calcified lymph glands at the hilum of each lung. The aorta showed only a small amount of arteriosclerosis. The thoracic duct was dilated and filled throughout with a milky fluid. There were a number of enlarged glands along the duct in the mediastinum. Just before the duct emptied into the left subclavian vein, it was pressed on by a mass of enlarged supraclavicular lymph glands, evidently causing stasis.

The brain was removed and, after being hardened in toto in formaldehyd, was sent to the state psychopathic hospital at Ann Arbor for examination. The report of Dr. A. M. Barrett was, "Slight leptomeningitis and cystic accumulations over the convexity."

Microscopic Examination.—The mass at the pyloric end of the stomach was found to be scirrhous adenocarcinoma infiltrating the muscle layers. Several portions of the lung

Fig. 2.—Section of liver under high power: edge of metastasis with adjacent liver cells, which have been distorted by pressure. Photomicrograph by Dr. W. P. Stowe.

were examined. One portion showed a hemorrhagic infarct with atelectasis about it; another portion showed a purulent exudate in the bronchi with scar tissue around them, some completely thrombosed blood vessels, and some blood vessels with thickened walls; and another showed small metastases consisting of carcinoma cells. Various enlarged lymph glands were examined and found to contain metastases. The yellowish areas in the liver when examined microscopically were found to be metastases. On section, the pancreas showed a certain amount of general atrophy and a number of small areas of recent hemorrhage. Some of these showed also abundant polymorphonuclear leukocytes. There were also, largely in the connective tissue, a few small areas of infiltration with small round cells. The spleen showed a thickened, dense capsule with dense trabeculae, and the walls of its blood vessels were dense and hyaline. There was a hypoplasia of the lymphoid elements. Sections of kidney showed an increased amount of connective tissue in the

cortex as well as in the medulla. There were a good many casts, the blood vessels were more or less hyalinized, and the glomeruli were somewhat shrunken. The heart showed probably an increase in connective tissue around the blood vessels.

COMMENT

The conditions found at necropsy were not anticipated during life, although carcinoma of the stomach was strongly suspected. The finding of chyle free in the thoracic cavity, or in the abdominal cavity, or in both, is quite uncommon.

Two articles on this subject have appeared in THE JOURNAL; the first, by Outland and Clendening,¹ and the second, by Tuley and Graves.² These articles are recommended to any one especially interested in this subject.

Outland and Clendening reported a case of chylous ascites and chylothorax due to carcinoma of the stomach. They referred to articles by Wallis and Schölberg,³ who had collected reports of 176 cases (including three of their own) of chylous and chyloform ascites. I have not been able to consult these references, but, if I understand it correctly, in sixty of these cases there was also chylothorax. Seventeen of the 176 cases were due to carcinoma of the stomach, and in three of these seventeen, the chylous fluid was found in the thorax as well as in the abdomen. Outland and Clendening collected reports of eleven more cases, of which one was due to malignant cysts in the pelvis and one to Hodgkin's disease. The others are ascribed to trauma, cirrhosis of the liver, appendicitis, nephritis, tuberculous peritonitis and heart and liver diseases.

Tuley and Graves report a case of chylothorax, chylous ascites and lymphosarcoma. They quote Sale⁴ as reviewing forty-two cases. The causes of these cases were given as new growths or tuberculous lymph glands in nine cases, thrombosis of the left subclavian vein, four cases, and secondary growths in the thoracic duct itself, nine cases. Other causes given were perforating lymphangitis, aneurysm of the duct itself, thrombosis of the duct, operation for removal of cervical glands, mitral disease, filariae, and inflammatory thickening of the mesentery.

I have not made a thorough review of the literature, but I have found the following articles since the publication of the two articles to which I have just referred. Lewin⁵ reported a case of chylothorax due to lymphosarcoma of the mesentery with metastases in various glands and in the thoracic duct. A case of traumatic chylothorax was reported by Derganz⁶ in 1915. Pisek⁷ reported a case of chylothorax in an infant aged about 2 months. The milky fluid was found on aspiration, and the infant recovered. Bonorino Udaondo and Castex⁸ reported five cases of milky ascites, some due to cancer of the stomach, and others to tuberculous peritonitis or other chronic processes.

It seems that malignant disease can be given as the cause of this condition in at least 10 per cent. of the cases. Outland and Clendening were unable to find the thoracic duct in their case, and they are inclined to

doubt the reports in which it is said to have been found dilated. In our own case, there was no difficulty in demonstrating the dilated duct.

SUMMARY

In a case of chylous ascites in a man, aged 72, the feature of special interest clinically was the appearance of enlarged glands in the left side of the neck a few weeks before death. Necropsy revealed milky fluid in the abdominal cavity, cancer of the stomach and metastases in the liver, lungs, mediastinal glands and the glands in the left side of the neck. The thoracic duct was dilated. Of the cases which have been reported with chylous fluid either in the thorax or abdominal cavity, or both, at least 10 per cent. have been due to malignant disease.

POLYPOID ADENOMA OF THE
STOMACH

REMOVAL BY GASTROTOMY

EMIL NOVAK, M.D.

Instructor in Clinical Gynecology, Johns Hopkins University
Medical Department

BALTIMORE

The frequency of cancer of the stomach is so very much greater than that of other gastric tumors that the benign neoplasms of this origin receive little attention in the diagnostic consideration of doubtful cases. Aside from their rarity, the accurate diagnosis of these benign tumors is rarely possible. Textbooks on medicine, and even the special works on diseases of the stomach, as a rule give scant attention to this group of tumors. Perhaps the most interesting neoplasms of this type are the adenomas.

The first undoubted case of adenoma of the stomach was that reported by Cruveilhier,¹ although earlier description of somewhat doubtful cases had been given by Morgagni and Lieutaud. Brissaud's excellent study² was based on the specimen from the case reported by Cruveilhier, which is preserved in the Dupuytren museum. One of the best modern articles on the subject is that of Menetrier.³ Among other excellent contributions are those of Hayem,⁴ Verse,⁵ Michel,⁶ Napp,⁷ Finney and Friedenwald,⁸ and Hauser.⁹

TYPES OF GASTRIC ADENOMA

A number of types of gastric adenoma have been described. Three groups may be recognized:

1. Polypoid adenoma, either single or multiple (*les polyadénomes polypeux*). In this type, the interior of the stomach presents one or more polypoid growths springing from the mucosa. As many as 300 have been reported in one case.

2. The so-called polyadenoma *en nappe* of Menetrier. This is characterized by involvement of large areas of stomach wall, measuring perhaps as much as

10 or 12 cm. in diameter. In this way large plaques are produced, rather than isolated polypoid out-growths.

3. The adenoma of the Brunner gland type, which was first described by Hayem in 1897. The point of distinction in this variety is that the gland tissue of the tumor, even though the latter be located in the stomach itself, is of the type of the Brunner glands which are found normally in the duodenum. This is the rarest of the three forms.

ETIOLOGY AND COURSE

Little of a definite nature is known concerning the etiology of this disease. It is, however, commonly believed to be most frequently the result of a chronic gastric catarrh. Napp believes that it is especially apt to be associated with the atrophic forms of chronic gastritis. While adenomas of the stomach may apparently remain for years and may cause no serious symptoms, it is generally conceded that they have a strong tendency to adenocarcinomatous degeneration.

CLINICAL SYMPTOMS

The disease is essentially one of advanced life, most of the reported cases having been observed in persons beyond the age of 50.

Perhaps the most extensive studies of the disease have emanated from pathologic institutes and have been based on specimens found at necropsy in patients who have died of other diseases. This is indicative of the infrequency with which the clinical diagnosis is made, for there are no distinctive symptoms. The usual manifestations of a chronic gastritis may be associated with severe epigastric pain, more particularly in the case of pedunculated growths, which may even cause pyloric obstruction. The specimen in the Dupuytren museum is said by Michel to show a polyp 10 cm. long which had partially traversed the pylorus, which it blocked. In the more marked cases of gastric polyposis, the roentgen ray may be of value in diagnosis.

SINGLE POLYPOID ADENOMA

The case which formed the incentive for the present summary was of the type of single polypoid adenoma. The size of tumors of this kind varies between wide limits. The largest one recorded is, no doubt, that of Chaput,¹⁰ which was as large as a fetal head at term. It was pedunculated and its surface showed no ulceration. Although reported as an adenoma, a suspicion is expressed by Hayem and Lion¹¹ that this tumor was really an epithelioma. There seems to be no special site of predilection of these growths, although they are perhaps more common in the pyloric region. Their consistency is rather firm, the cut surface often being dry and at times almost lardaceous.

Microscopically, these tumors are formed chiefly of the overgrown glandular tissue of the gastric mucosa. The glands themselves are commonly of the pyloric type and are lined by cylindric epithelial cells, which are sharply marked off from the basement membrane. The nuclei are placed close to the latter, and goblet cells are numerous. A greater or less degree of cystic distention of the glands is common, and may be so marked as to give a honeycombed appearance to the cut surface of the tumor. The interglandular substance is a dense connective tissue, often showing moderate round-cell and leukocytic infiltration. The glandular tissue shows no tendency, in benign growths, to penetrate beyond the muscularis mucosae, a point emphasized by Napp.

SURGERY

Little need be said concerning the surgery of these growths in the rare instances in which they are discovered, for the surgery involved in their removal is in itself comparatively simple. In Chaput's case, already referred to, the large tumor which was found was removed by gastrotomy, as was done in the case of the much smaller growth in my own patient, as is described below. The same procedure was carried out in the case of Gibson¹² and also in that of Blake.¹³ Both of these resembled my own in every way, so far as may be judged from the very brief and incomplete reports made in the course of a discussion at a meeting of the New York Surgical Society. The case of Lange, referred to by Hayem and Lion,¹¹ was one of the *en nappe* type, necessitating partial gastrotomy. These cases were all successful.

REPORT OF CASE

History.—E. B., a married woman, aged 45, seen in consultation with Dr. Benjamin O.

McCleary, August 10, with nothing of significance in her family history, having enjoyed good health up to about four or five years before with the exception of infrequent attacks of tonsillitis, for the past four or five years had suffered with a gnawing pain in the epigastrium, occurring, usually, immediately after eating. There was also a great deal of eructation, but no vomiting.

Seven weeks before I saw her, the patient had been taken with a severe attack of pain in the right hypochondrium, associated with marked tenderness and some rigidity over this region. Morphine was necessary to control this pain, which Dr. McCleary felt was due to a cholecystitis. This attack had lasted for a number of hours and then subsided. Since then, the patient had continued to suffer with stomach symptoms, as noted above. The day that Dr. McCleary and I saw her she had suffered, early in the morning, an attack almost exactly similar to the one just described. The general condition was good, although there was some tendency to prostration. Vomiting had occurred once or twice. The pain over the gallbladder region was described as agonizing,

Polypoid adenoma of the stomach: a, tumor on posterior wall of stomach, and incision for its removal; b, gross appearance of tumor, with pedicle; c, cut surface of growth, showing cystlike gland spaces.

10. Chaput: Bull. Soc. anat. de Paris 70:534, 1895.
11. Hayem and Lion: Traité de médecine, Brouardel, Gilbert and Thoinot, 1913, p. 413.

12. Gibson, C. L.: Ann. Surg. 45:130, 1907.
13. Blake, J. A.: Ann. Surg. 45:130, 1907.

and tenderness was definitely localized over this point. I concurred with Dr. McCleary in the diagnosis of cholecystitis and advised operation.

Operation and Results.—Aug. 14, 1919, the usual right rectus incision was made over the gallbladder. The gallbladder was found to be tightly distended and very thick walled. It did not, however, contain stones. Before the gallbladder was opened, it was considered advisable to explore the stomach and duodenum. There was no induration or other evidence of ulcer in either the pylorus or duodenum. Within the cavity of the stomach, however, some distance from the pylorus, could be felt a hard globular mass, about the size of a small walnut, which could be moved about very freely. Careful palpation revealed what seemed to be a thin, cordlike pedicle. The stomach was opened, as indicated at *a* in the accompanying illustration, and the tumor easily delivered into the incision. It was about 3 cm. in diameter and was attached by a pedicle 2 cm. long and about 0.5 cm. wide to a point on the posterior wall just below the lesser curvature of the stomach, somewhat closer to the pyloric than to the cardiac orifice (*a*). The tumor was removed by ligation of its pedicle and severing with the electrocautery. The gallbladder, being obviously diseased, was drained in the usual manner.

The patient made an uninterrupted recovery and is now enjoying good health.

Pathologic Report.—The tumor was almost globular in shape, measuring about 3 cm. in diameter, the attached pedicle being 2 cm. in length and about 0.5 cm. in diameter. The surface showed a slight tendency to lobulation in places (*b*). For the most part it was quite smooth, although there were several small areas of erosion. The tumor, on being cut into, was found to be quite dense and dry, being apparently made up, for the most part, of connective tissue. The latter, however, was studded with numerous cystlike spaces, evidently dilated glands of varying size. This is well shown at *c*. The gland tissue had no tendency to extend beyond the muscularis mucosae.

Microscopically, the lining epithelium was found to be of the usual columnar type, containing many goblet cells. In many places, however, it was eroded. Beneath the epithelial surface, and especially in the areas of erosion, there was marked injection of the blood vessels, with marked infiltration of leukocytes and small round cells. The gland tissue beneath the surface was arranged rather irregularly. In places the gland acini were rather closely packed, their outline being regular and the lining epithelium being similar to that found on the surface. Between the glands in these areas there was also much inflammatory infiltration. In other parts the glands were enormously dilated, forming cysts of considerable size, the largest being about 1 cm. In no part of the tumor was there any transformation of the epithelium which might suggest malignancy, nor was the gland pattern malignant in type. The tumor was apparently a benign pedunculated adenoma.

26 East Preston Street.

Factors Essential to Recovery from Tuberculosis.—Two things more frequently than any others work against the recovery of persons who have tuberculosis. One is that in so many cases of tuberculosis the true nature of the disease is not recognized while it is in the early stage, when it is much more easily cured than it would be later. The other is that many persons refuse to believe that they have tuberculosis until the evidence is so plain that the diagnosis of the physician is no longer needed.—*Bull. Maine State Dept. of Health*, October, 1919.

POLYDACTYLISM AND THE PHENOMENON OF REGENERATION

GEORGE F. ARPS, PH.D.
COLUMBUS, OHIO

Cases of polydactylism have been recorded since early times. Annandale¹ sees in Chaldean illustrations evidences of cases of supernumerary digits. Illustrations of double hands on each arm may find their origin in genuine cases of polydactylism. Beginning with the seventeenth century on down to the present, more or less authoritative cases multiply the records.

Many of the recorded cases¹ are extremely interesting. Forster sketches a hand with nine fingers and a foot with nine toes. Voight records an instance of thirteen fingers on each hand and twelve toes on each foot, making a total of fifty digits. Saviard, in 1687, reported the case of an infant with forty digits, ten to each member. It is not evident from the reports whether or not, in any of the foregoing, the extra digits constituted well developed organs. Meckel, however, offers a case in which a man possessed twelve fully developed fingers and toes. Scherer records the case of a girl baby, normally formed, with seven fingers on each hand, all united and bearing clawlike nails. On each foot there was a double hallux and five other digits, some of which were webbed.

HEREDITARY CHARACTER

According to Davenport² polydactyl traits appear to be inherited in nearly typical fashion, as indicated by the pedigree of a family cited by Lucas. Reaumer traces the influence of heredity in the Kelleia family of Malta through five generations. The trait is especially persistent in consanguineous marriages, illustrated by the family of Foldi in an Arabian tribe. In this stock, all acknowledged offspring possess twenty-four digits. An infant born with the normal number of digits is recognized as a product of adultery and is immediately sacrificed. The inhabitants of the village of Eycaux, France, have similarly perpetuated the anomaly in that the village was isolated by its inaccessible location in a mountainous region.

This anomalous phenomenon is not confined to man alone; apes, dogs, fowls and other lower animals possess it. The reported cloven-hoofed horses of Alexander and Caesar are suggestive cases of this trait.

REPORT OF CASE

History.—An Alabama negro boy, aged nearly 21, who, up to the time of his induction into the service of the army, had been employed as a section hand, attracted the attention of the psychologists at Camp Sherman because of his failure to negotiate successfully the Beta examination (for illiterates). The presence of the supernumerary digits was detected during the progress of a special individual examination.

1. Gould, G. M., and Pyle, W. L.: *Anomalies and Curiosities of Medicine*, Philadelphia, W. B. Saunders, 1897.
2. Davenport, C. B.: *Heredity in Relation to Eugenics*, New York, Henry Holt & Co., 1915.

Fig. 1. Pedigree of polydactylism: Shaded symbols represent affected persons; surplusage of digits limited to the hands, and never more than one extra digit on each.

A rather small but well-formed sixth digit was found on each hand at the knuckle of the little finger. Both digits were attached at the sides in the same relative position, the upper part of the attachment being on a level with the joint, while the lower point of attachment was about 1 inch distant, along the outer edge of the metacarpal bone. The two digits were exactly the same size and were identical in all other particulars. There was no bone and a very low degree of sensitivity. They were incapable of voluntary movements. Markings peculiar to the last phalangeal point were present, as were also small finger nails proportionate to the size of the digits. In all of these respects the two digits were symmetrical throughout. The identity was unvarying as to skin color and contour.

Family History.—The determiners of the polydactyl trait were not carried on the maternal side; the subject remembered seeing the deformity definitely only in the case of his father, his brothers, sisters and the children of his oldest and youngest sisters. He was very certain of these three generations, and appeared to remember having seen these "rooster's spurs" on his grandfather and one of his uncles. Two brothers, five sisters and two children of two of the sisters continue the peculiarity; eleven descendants, including the father and himself, carry the determiners of this trait.

Regeneration.—The subject reported that his father had the supernumerary digits removed, and that since then it has been necessary to trim them off, as they grow continuously. This fact is strongly indicative of the phenomenon of regeneration of parts, characteristic of lower forms of life—the regeneration of a lost leg in a crab, for example. We may find here some support for the view that in the fertilized ovum is found an aggregation of diversified materials known as formative stuffs, each of which is deterministically specific in the direction of structure. Speculation as to the bearing of this phenomenon on the theory of epigenesis versus that of evolution is left to the cell specialist for indulgence. Whether the entire digit would be regenerated if permitted to grow is, so far as I am aware, unknown.³

Health History of the Subject.—He reported that he had had but few of the diseases of childhood. He confessed promiscuity and acknowledged having had gonorrhea and bubo, once each. He was not a drug addict, nor did he use tobacco or alcohol. There were present prognathism, receding forehead and narrow skull usually found in the negro; but no unusual stigmas were found save the existence of supernumerary digits.

Mental Ratings of the Subject.—The range of information of the subject was extremely limited, since he had never attended school and could neither read nor write. Mental ratings were obtained by means of the short performance scale and the short Yerkes-Bridges point scale. In the former examination the subject did well in the ship, manikin and feature profile tests, fairly well in the digit symbol test and on the mazes, but very poorly in the remainder of the examination. The result obtained by the short point scale method are regarded as the more reliable, and these indicate a mental age of 10.3 years.

The subject of this report was recommended for general military service.

FOCAL INFECTION AND ITS RELATION TO OBSTETRICS

JOHN E. TALBOT, M.D.

WORCESTER, MASS.

Given a focus of infection in a pregnant woman, there are certain well-known possibilities. A focus of infection means a colony of pathogenic bacteria within the tissues of the body in the process of active multiplication. This colony of bacteria is kept alive by the destruction or digestion of the neighboring tissues of the body, and there is a by-product of this growth known as bacterial toxin which is known to be antagonistic to the proper functioning of the body cells. Any such colony may be the point from which

bacteria may migrate into the blood stream and thus be scattered to different parts of the body, to cause disease in organs remote from the original focus. It is generally believed that such migration is of only occasional occurrence, whereas the absorption of the bacterial toxins into the blood stream is to a certain degree always present. I do not believe that focal infection is the only etiologic factor in the several complications of pregnancy which are here discussed. It does, however, have a tremendous influence on obstetrics; many complications, hitherto obscure as to etiology, can be attributed to the presence of a focus of infection. From a prophylactic standpoint, every obstetrician should study his patients to ascertain whether any such focus is present, and have it removed before it does harm.

The reader should interpret the term "focus of infection" as meaning exactly what it says, regardless of the location. I emphasize the teeth simply because I believe that they harbor these foci more commonly than do the tonsils, sinuses, ears, etc., and that they are actually of greater potential danger than the others. The roentgen ray has demonstrated that a high percentage of "saved teeth" have abscess formation at the ends of the roots. An

abscess at the end of a crowned or pivot tooth is a different thing from a decayed tooth. In the first case the abscess must necessarily drain into the blood stream; in a decayed tooth there may be some drainage into the mouth and some into the blood stream. The former is therefore the more dangerous.

My subject naturally divides itself into two parts: (1) those complications which may be the result of a temporary bacteremia or septic embolus, and (2) those complications which may be the result of the presence of the toxins of chronic sepsis in the blood of a pregnant woman.

BREAST ABSCESS

It is impossible to produce conclusive evidence that any given breast abscess was due to a septic embolus

Fig. 2.—Size of little finger and digit, relative position of supernumerary digit, and place of attachment; left hand, palm upturned.

3. Unfortunately I was unable to confirm by direct observation the reported phenomenon, which, if correct, is most unusual and must be regarded with extreme skepticism unless confirmed by other investigators.

which had freed itself from a focus of infection elsewhere. However, it has undoubtedly been a common experience of many to observe a breast abscess develop most mysteriously without sore or cracked nipples and in the presence of painstaking care of the nipples. In one patient¹ a breast abscess developed fourteen days after delivery, although the baby died, and the breasts, which had not been used, had had careful treatment. In this case and in others I have been able to demonstrate a focus of infection elsewhere.

Breast abscess is much less common than that syndrome of symptoms classified as plugged duct or threatened breast abscess. It has been my experience to find most of these cases associated with a demonstrable focus of infection. I believe that they are for the most part actual infectious processes, and that the term "threatened abscess" is the correct one.

When we take into consideration how frequently the mother's milk becomes affected, with resulting illness of the baby due to these threatened abscesses, we must realize the far-reaching effect of an infected tooth, which may be the cause of illness in the baby through lack of proper breast milk or through nursing milk with bacteria contained therein.

I was called to see a breast-fed baby which was not gaining properly, crying a great deal, and showing little pustules on its head and body. I found that the mother had had two recent attacks of "threatened breast abscess." A roentgen-ray examination of the teeth revealed several apical abscesses. The milk remained so poor that I was forced to have the baby weaned.

Pyelitis is another complication of pregnancy which can frequently arise from a focus of infection. That pyelitis is known to be a more frequent complication of pregnancy than formerly can well be explained on the recent increase in the number of undrained foci of infection which have resulted from dental practices.

Certain obstetric patients, few in number, to be sure, have been known to die of puerperal sepsis in spite of careful aseptic treatment.² The causation has always remained a mystery; but if a focus of infection can be demonstrated in such a case, would it not be more reasonable to regard this as the cause than to assume that bacteria in the vagina should suddenly assume virulence sufficient to be fatal?

Women have died of pulmonary embolus before delivery. Thrombus formation implies infection in or around a blood vessel. If this occurs in an otherwise apparently healthy person, where does the infection enter? With a focus of infection demonstrable it is apparent that, on the principle of a temporary pyemia, it may be the primary cause.

One principle which may have a bearing has been established: bacteria injected into the blood stream of an animal, otherwise aseptically wounded, have a tendency to appear in and infect the aseptic wound or weakened part. It is also true that tissue in the process of production has a weak resistance to infection. If, therefore, bacteria in the blood stream reach the placenta, it is not improbable that they may cause inflammation in the villous membrane. The sluggishness of the blood stream at this point is a factor which tends to improve the opportunity for such a process.

It is my belief that a very large proportion of the uninduced miscarriages are due primarily to this cause. If the inflammation is sufficient in amount, it would result in rupture of the villous membrane with the formation of a hematoma, which in time may separate the placental tissue from the uterine surface sufficiently to cause internal, concealed hemorrhage or external hemorrhage, according to the location of the inflammatory process in the placenta.

Threatened miscarriage may be the result, or, if the hemorrhage is sufficient to terminate the pregnancy, a miscarriage is the result. I have been able to demonstrate foci of infection in a high percentage of those cases of miscarriage which have been in my charge.

So far as recent teaching has gone, *Spirochaeta pallida* has been granted the exclusive privilege of passing the villous membrane and infecting the fetus. Syphilis has stood out as the one disease which is clearly inheritable, the fetus actually containing the active infective agent. Why should the spirochete enjoy this exclusive privilege? There is evidence accumulating that this is not so, however, and once it is proved that other bacteria pass the villous membrane, then a focus of infection capable of throwing bacteria into the maternal blood stream becomes a danger and a menace to the life and welfare of the fetus.

Hydramnios, so frequently associated with the malformed and macerated fetus and with toxemia of pregnancy, is probably a secondary result of the same infective process.

Nearly every baby which in my experience has developed hemorrhage of the new-born has come from a mother in whom I have been able to demonstrate foci of infection in the teeth; and a high percentage of such mothers have shown some signs of toxemia during their pregnancy.

Pustular eruptions are fairly frequent in children not more than 48 hours old. Such cases of this as have come under my observation have been associated with foci of infection in the mother. Likewise, pustular eruptions are not infrequent sequelae to threatened breast abscesses.

If it can be proved, therefore, that the bacteremia originating from a focus of infection can result in inflammation of the placental tissue or villous membrane, a great many of the tragedies of obstetrics, hitherto unexplainable, can be given a reasonable etiology.

COMPLICATIONS OF PREGNANCY FROM TOXINS OF CHRONIC SEPSIS

Every focus of active bacteria within the body produces a by-product—toxin—which, in sufficient concentration is antagonistic to the proper functioning of the body cells. Disease is the outward manifestation of the effects of this toxin in the body.

The fact that a few days elapse before symptoms become apparent following infection is proof that toxins in lesser degrees of concentration are present in the system, doing damage gradually, and that the symptoms which declare the disease may be said to be the cumulative effect of low concentration of toxin, or the effect of the increase in the amounts of toxin to the point of causing symptoms. It must be a fact that these toxins in lesser degrees of concentration are injurious and will produce results in time, just as the lesser degrees of lead poisoning produce symptoms after the lapse of time.

1. Talbot, J. E.: A Theory on the Etiology of Toxemia of Pregnancy With or Without Convulsions, *Surg. Gynec. & Obst.* 28: 165-174 (Feb.) 1919.

2. The Prevention of Puerperal Sepsis, editorial, *Boston M. & S. J.* 179: 104 (July 18) 1918.

It would be a reasonable conclusion, therefore, that any focus of chronic sepsis must be a hindrance in some degree to the proper functioning of the body processes. By taking up those symptoms which manifest themselves as the result of high concentrations of bacterial toxin in the blood and working backward, we may thereby pick out those organs of the body which are undergoing damage during the prodromal stage of a disease. The situation is probably similar to the wear on the bearing of a machine. The signs of this wear do not appear until there is sufficient injury to cause wobbling or a break in the bearing. It is fair to assume, therefore, that if the kidney or the liver are the usual organs injured in a given disease, these organs are without doubt hindered in their proper functioning by these toxins when in low concentrations.

The fact that the urine of a severely sick person shows evidence of acute kidney irritation suggests that toxins of various types are damaging the kidney parenchyma. It is equally true that certain bacteria have a special tendency to cause damage to the kidney—witness the frequency with which scarlet fever is followed by kidney injury. This injury is generally not an immediate result, but a late result of the disease. In our endeavor to find the primary cause of the kidney inefficiency in toxemia of pregnancy and eclampsia, it seems significant that a streptococcus is so frequently associated with the scarlet fever lesions in the throat, and that the streptococcus is perhaps the most common type of bacteria in tooth root abscesses and chronic tonsillar abscesses.

Dr. James L. Huntington³ has reported the case of a primipara who on her first visit showed a blood pressure of 150, which returned to normal only to rise again three months later. This rise was soon followed by a severe attack of abdominal pain and the appearance of jaundice and blindness. This was followed by external hemorrhage. The systolic blood pressure was 170. The diagnosis of detached placenta was made and verified by an abdominal operation, at which time a cesarean section was performed. A catheter specimen of urine showed a large trace of albumin. Forty-eight hours after the operation the patient died, a temperature of 103 occurring within twenty-four hours after the operation. The liver showed much destruction, and a streptococcus was recovered from the peritoneal fluid.

If this patient had recovered, the case would have passed as a severe toxemia of pregnancy accompanied by complete detachment of the placenta. The rise of temperature so soon after operation suggests strongly that the source of infection, which turned out to be a streptococcus, was in the system before the operation. I believe it was the activity of this streptococcus which was the cause of the condition. The elevation of the blood pressure three months before probably denoted the activity of this bacterium in some undetermined focus of infection. In such a case we are dealing with the fulminating type, the ordinary case of toxemia being of the same nature but of lesser degree of intensity.

La Vake,⁴ who believes in the infectious basis of toxemia of pregnancy and eclampsia, quotes the work of Warnekros, who obtained eighteen positive blood cul-

tures out of twenty-five taken antepartum in toxemia cases. The streptococcus group is prominent in the kinds of bacteria recovered by him. This evidence forms a basis for my belief that some of the bacteria of the streptococcus group may have a specific power to injure the kidney function and kidney parenchyma.

The metabolic processes of a pregnant woman are much in excess of the normal. This increase in activity must incur a corresponding increase in the metabolic waste products that must be excreted. In order to prevent a backing up of these waste products in the system, the kidney reserve power must be called into play. If, however, the kidney function is hindered by the presence of the toxins of chronic sepsis in the blood stream, it is reasonable to assume that there may be a time when the hindering effect of these toxins may be sufficient to cause a failure on the part of the kidneys to eliminate properly the increasing amount of waste products from the developing pregnancy. We are, therefore, in a situation similar to that of a city with the outlet of the sewer partially plugged. The remaining outlet might be sufficient to take care of the sewage of the city, if it were not a growing city; but the increase in the amount of sewage to be removed soon overwhelms the impeded outlet until there is backing up, with resulting damage coming, not from the reduced outlet, but from the unre-moved sewage itself. We do not have to assume any special poison resulting from the developing pregnancy, for we know that excretory products retained in the system are injurious to that system. The symptoms which go to make up the disease of toxemia of pregnancy are, I believe, due to the retained waste products of the normal physiologic metabolism. The reported work of Slemmons⁵ shows, likewise, a retention of nitrogenous waste products in the blood of toxemic and eclamptic patients.

That a large proportion of uninduced miscarriages are due primarily to foci of infection is shown: first, by the frequency with which miscarriage appears in the obstetric history of toxic or eclamptic patients; secondly, by the frequency with which antepartum hemorrhage, by which I mean hemorrhage coming on after conception, is associated with toxemic or eclamptic patients, and thirdly, by the frequency with which infarcts in the placenta are found on the edge of the placenta, frequently showing an indentation in the circular outline of the placenta which strongly suggests an injury at that point which stopped the growth of the placenta in that direction.

These three observations can be successfully correlated if we assume that there is a primary focus of infection in the system. If the infarct can be interpreted as a point of damaged placenta with nature's healing process superimposed, and if we assume that that damage was primarily caused either by the lodgment of a small embolus of bacteria or by the toxins of sepsis in the blood stream, it is not at all difficult to understand why these three observations are associated. It is also plain that it is not impossible to have miscarriages, antepartum hemorrhage and infarcts in the placenta without other toxic symptoms.

Suppose that there is a septic embolus in the blood stream of the pregnant woman, and that this embolus reaches the placenta. The sluggishness of the blood stream in this organ would improve its opportunity

for finding lodgment in the villous membranes. This inflammatory process, if located near the edge of the placenta, would cause swelling and local thrombosis in the placental tissue. If this swelling is sufficient, it is possible that there may result a local hematoma, which is in reality a small area of internal, concealed hemorrhage. Should this hematoma be large enough to cause a rupture between the edge of the placenta and the uterus, there would be an external hemorrhage which would make its appearance in the vagina only when it was sufficient to dissect its way downward between the chorion and the uterine wall to the external os. Thus, we might have numerous infarcts formed without any external hemorrhage. Likewise, we might have numerous infarcts formed without any accompanying evidence of toxemia of pregnancy.

If this injury to the placenta is in the middle of the placenta, an infarct may form without symptoms unless the injury is sufficient to dissect sufficient of the placental tissue to terminate the life of the fetus. In such a case the miscarriage may not result for weeks after the injury.

The following case is an example of this kind:

A woman, aged 39, who had a bad upper left wisdom tooth and several devitalized teeth, had been pregnant three times. The first pregnancy went to full term and was said to be associated with uremic poisoning and the puerperium complicated by pyelitis. The second pregnancy resulted in a miscarriage at two months associated with edema. The third pregnancy resulted in a miscarriage at five months, followed by several months of anemia.

A fourth pregnancy resulted in a miscarriage at four months. Before this miscarriage occurred she reported to me that she had had a sudden onset of severe pain in the right lower quadrant which had lasted about three days, but was almost gone at the time she reported to me. No further symptoms occurred until she began to bleed profusely, one month later. The vagina was packed and the patient taken to the hospital. When the pack was removed, the placenta came away with the membranes intact. The whole center of the placenta was destroyed and showed signs of old hemorrhage.

The pain which the patient experienced the month before was probably caused by an area of internal concealed hemorrhage in the middle of the placenta. This patient had what was in all probability a toxemia with her first baby; none of her subsequent pregnancies have been sufficiently long to develop real toxemic signs. This case also represents an example of the association of miscarriage with toxemia of pregnancy.

Antepartum hemorrhage due to premature detachment, partial or complete, has long been recognized as a common accompaniment of toxemia of pregnancy. I believe that this phenomenon is due primarily to an injury done the placenta either by a local infectious process or by the toxins of sepsis in the blood stream, followed by a hematoma which may dissect the whole or a part of the placenta away from the uterine surface. Dr. Huntington's case, cited above, is a good example of this in its worst form.

A case recently reported by Cornell and Earle⁶ of Chicago demonstrates exactly this *modus operandi* of a miscarriage:

A multipara, aged 36, in her sixth pregnancy had some bleeding at the end of the second month. An examination gave reason to believe that an extra-uterine pregnancy was

present. Accordingly, the abdomen was opened and it was found that the patient had a bicornate uterus; in the right horn was a fibroid, in the left, a pregnancy. It was decided that hysterectomy was the best procedure, and the specimen was removed in toto.

This set of circumstances, that is, the removal of a uterus following so closely on a threatened miscarriage, is therefore exactly what could be desired in order to get a proper examination of the placental tissue following this threatened miscarriage.

The pathologic report is most complete:

The only abnormal feature of this placenta is the abundance of necrotic areas in the decidua adjoining the intervillous space. The margin of these areas is densely infiltrated with leukocytes. . . . They show profound necrosis centrally, there may be some hemorrhage, and there is always a margin densely infiltrated with polymorphonuclear leukocytes. . . . One small area . . . showed . . . a villous with edematous stroma. These observations point to a beginning abscess formation with spreading of the infection to the ovum. Slides stained with Gram's stain afford some inconclusive evidence of the presence of gram-positive cocci, but the histological appearance of the necrotic areas points clearly to their infectious origin.

Where did this infection come from? Besides mentioning that the patient had very bad teeth and some enlarged cervical lymph glands, the report tells of an acute infection, a "cold," which had lasted three weeks, and that the bleeding followed soon after this infection. The enlarged lymph glands in the neck might have become enlarged as a result of infection either in the teeth or in the tonsil. In all probability it was the infection in the tonsil which was the focus which threw off bacteria into the blood stream. I do not believe that the bad teeth can be thrown out of this case as a possible source of infection, unless the patient had other evidence of chronic disease of the tonsils. In her history she has stated that her first baby died of vomiting blood and her third pregnancy was a miscarriage. I would, therefore, read into her history a story of chronic infection either in her tonsil or in her teeth, antedating her first pregnancy. The incidence of a hemorrhagic baby associated with a later miscarriage, when viewed from the light of other experiences, forms an entity which justifies this supposition. If this is the true explanation of partial or complete detachment of the placenta, there is no reason for seeking another to explain the miscarriages which so frequently occur in the history of toxemic patients, or in patients who have a miscarriage without a demonstrable cause.

The three cases of pernicious vomiting of pregnancy which have come under my observation during my service at Memorial Hospital were so striking that I have classified this complication of pregnancy among the others attributed to the effects of chronic sepsis. In two of the cases observed, the mouth was full of carious teeth, the gums markedly inflamed and full of pus.

In one of these cases, twelve extractions of those teeth which were flush with the gums were made in the hope that the supply of toxins might be decreased sufficiently to improve the condition. In forty-eight hours the pulse had risen from 100 to 120 without marked improvement in the vomiting, and it was compulsory to terminate the two and a half months' pregnancy.

In the second case the patient was in extreme emaciation, having been sick for six weeks before entering the hospital. A five months' pregnancy was terminated and a macerated

6. Cornell, E. L., and Earle, W. C.: Uterus Bicornis Unicollis with Two Ova Implanted in One Horn and a Fibroid in the Other, *Surg., Gynec. & Obst.* 29: 485 (Nov.) 1919.

fetus removed. As in the other case, the mouth was a mass of infection. On discharge, recommendation was made that these teeth be extracted. However, this was not carried out, and about one year later the patient appeared at the hospital again and had to be curetted for an incompleting miscarriage.

The third patient appeared at the hospital on account of severe vomiting at the second month of pregnancy. The case had previously been diagnosed as tuberculous kidney after catheterization of the ureters six months before the patient became pregnant. Abortion was recommended and performed in this case.

In a recent article, Dr. Eugene S. Talbot⁷ says:

The number of focal infections and disturbances from faulty root fillings, local and systemic, is appalling. The average dentist, not being grounded in pathology, does not and cannot appreciate the seriousness of his faulty treatment. A different method of root filling must be immediately instituted or devitalized teeth must be extracted. A rule which I have adopted is that a patient's health is worth more than all the natural teeth.

From time to time, in the past thirty years, I have repeatedly called the attention of the profession to the fact that modern dentistry is producing more disease than any other one cause. The profession is beginning to realize the truth of this statement. Since the first dental college was established, there has gradually developed a method of practice of mechanics regardless of pathologic results. The method of practice, at best, has benefited the individual patient only for the time being. . . . Since our present methods of procedure are faulty, we must resort to radical changes in treatment and devote our entire attention to preventive measures.

CONCLUSION

One needs to be a believer in only a part of the statements made to be impressed with the seriousness of the situation and with the need for the removal of all known foci of infection when associated with pregnancy.

28 Pleasant Street.

TREATMENT OF DENERVATED MUSCLE *

FRANK A. HARTMAN, PH.D.

Professor of Physiology, University of Buffalo Department of Medicine

BUFFALO

AND

W. E. BLATZ, M.A.

TORONTO

In 1841, Reid¹ advanced the theory that the atrophy of denervated muscle was caused by inactivity. He found that in the frog, a denervated muscle that was exercised daily by galvanic stimulation did not lose weight. Untreated muscles were thought to decrease one half, but it is now known that frog's muscle does not atrophy nearly so rapidly as Reid believed.

Brown-Séquard,² working with rabbits, also came to the conclusion that galvanic stimulation prevented atrophy. The work of these investigators led to a general adoption of the disuse theory. This theory served as a foundation for all later treatment. Massage and passive movements were found to promote circulation

in normal muscle, and therefore it was thought that similar treatment would benefit denervated muscle.

At the present time, the generally accepted methods of treatment for denervated muscles are either massage or electrical stimulation. Indeed, until the investigations of Langley and his collaborators, no experimental work seriously questioned the value of massage or electrical treatment in a muscle whose nerves had been destroyed. Although Schiff,³ from observations which he had made on the tongue and the limb, concluded that fibrillation is a general phenomenon in muscle after nerve section, Langley⁴ was the first to suggest that the atrophy is due to continuous fibrillation. Fibrillation begins four or five days after nerve section, and persists until some of the regenerating fibers make connection with the muscle. Such incessant activity might well cause wasting of the muscle. Langley and Kato⁵ were able to check fibrillation by the intravenous injection of considerable amounts of calcium chlorid. They demonstrated no change from the feeding of calcium lactate. Ionization with calcium chlorid stopped fibrillation, but produced such trophic changes as to make its use inadvisable.⁶

The time-honored treatment by massage has been studied in a series of researches by Langley and his co-workers.⁷ Their method has been to denervate two corresponding muscles in the same animal. After a period of treatment of the muscle on one side, the animal was killed and the corresponding treated and untreated muscles were carefully dissected out and then weighed. In this way, some idea of the relative amount of atrophy could be determined. They had to take into account the variations that might normally occur in the relative weights of the right and left muscles at the beginning. This method, moreover, assumed that the weight was a true measure of the unatrophied muscle because the connective tissue could not be ruled out.

Langley and Hashimoto⁶ reach this conclusion:

Reviewing the effect of the various forms of treatment we have tried, there is, we think, only one which gives any hope of considerably reducing the rate of atrophy, viz., ionization with a potassium salt, and that is slender, for an (apparently) positive result was only obtained in one out of three experiments.

The general impression we get from our experiments, and from those made earlier by one of us, is that none of the methods of treatment of denervated muscle now in use—passage of galvanic current, production of contraction, passive movements and massage—can have more than a slight effect in delaying muscle atrophy.

In a recent study,⁸ we have investigated the effects of massage on denervated muscle. Instead of depending entirely on the weight for comparison of the treated and untreated muscles, the work capacities were also determined. However, the method then used necessitated a sacrifice of the rabbit at the end of the functional test, since the muscles were dissected out for the purpose. The gastrocnemii were dissected free, with as little disturbance in the circulation as possible, and then with the leg in the foot-down position, the Achilles tendon was fastened to a weight pan while the tibia was clamped. The muscles also were weighed.

There was found to be a considerable discrepancy between the comparison by weight and the comparison

by function. With the functional test as the method for comparison, the massaged muscles were found to be stronger in 62 per cent. of the animals treated (thirty-seven rabbits). However, in view of our ignorance of the relative capacities of the two sets of muscles before treatment, a small preponderance of power in the treated muscles was considered inconclusive.

Believing that the functional test is a better method for determining the amount of active muscle tissue than that by weight, we have recently devised a method which makes it possible to study the relative strengths of the muscles at frequent intervals in the same rabbit. Thus, in the present research we have studied the effects of massage in sixty rabbits and the effects of galvanic stimulation in twenty-four, in all cases testing the treated and control muscles from every ten to fourteen days.

METHODS

Under anesthesia the flexor muscles below the knee in each hind limb were denervated either by crushing the sciatic nerve with a hemostat whose jaws were ground smooth, or by cutting the sciatic. Before cutting the nerve, a fine (000) cat-gut suture was passed through it at two points, a few millimeters apart. The nerve was then cut, and the two ends were drawn together by tying the suture. One suture included the two contiguous branches of the sciatic.

In a later series of rabbits in which we wished to delay the suturing, the proximal end was prepared in one of three ways: first, enclosed in a small sterile rubber tube which was doubled back and ligated to the muscle; second, enclosed in a tube which extended along the course of the muscle toward the knee, the tube being long enough to insure carriage of the growing proximal end beyond the peripheral cut end; third, the proximal end reversed and sewed to muscle without a tube.

The gastrocnemius muscle groups were tested on the day following the operation while the animal was lightly anesthetized with ether. The animal was placed in a ventral-side-down position on an animal board, with the hind limbs hanging freely over the end. Both hind feet were tied to aluminum sandals which swung from rigid horizontal rods (Fig. 1). The freely moving end of each sandal was attached by string to a scale pan and lever. The apparatus was so arranged that a record of the contraction could be made on a kymograph. The muscles were caused to contract by a supermaximal galvanic stimulation, the inactive electrode being placed on a moistened shaved area at the midline just in front of the tail, while the active electrode touched as nearly as possible the motor point for the gastrocnemius similarly prepared. A series of contractions at a wide range of loads with supermaximal

stimulation (30, 40 or 50 volts) indicated very well the relative strengths of the two muscle groups. The amount of work calculated at the optimum load was used as a basis of comparison for the functional capacity of the muscles. Each rabbit was tested in this way at frequent intervals throughout the course of the experiment.

TREATMENT

Massage.—The right limb of each animal was massaged for a certain period of time each day, varying from two to twenty minutes. Both right and left limbs were given passive movements three times at each treatment to aid in preventing stiffening of the joints. The feet were always encased in aluminum boots.⁸ Masseuses from the School of Massage, Hart House, Toronto, gave this treatment.

Galvanism.—A series of twenty-four animals was treated with the galvanic current. This treatment consisted of shocks produced by a metronome connected in the circuit, the aim being to secure a certain magnitude of contraction. This magnitude and the duration of the treatment varied in different rabbits. The contractions were roughly classified into minimal, moderate and vigorous. The duration varied from five to fifteen minutes, but in many cases each alternate minute was allowed for rest. The metronome made and broke the circuit once each second. The voltage ranged from 6 to 30 with 1 to 10 milliamperes of current. A greater voltage was required to produce the same magnitude of contraction as degeneration progressed.

RESULTS AND COMMENT

Both the electrical and the massage series may easily be discussed together, for neither treatment appeared to produce any greater effect than the other. This is easily explained when it is considered that the treated limb on the whole did not appear to be any better off than the control limb.

Within the first month after denervation, there was a very marked drop in the power to respond to galvanic stimulation. This occurred alike in the two limbs.

In addition to the series in which the nerves were crushed or cut and immediately sutured, we have studied a series of forty-one rabbits in which the proximal end of the nerve has not been permitted to unite with the distal end for periods varying from thirty to 100 days. These animals were treated either by massage or by electricity. The treated muscles lost their galvanic response just as quickly as did the controls. Moreover, neither massage nor electricity caused the denervated muscle to recover from the diminished response. Fourteen per cent. of the rabbits did show a slight advantage on the treated side, but it was no more than would be expected from accidental variation.

Fig. 1.—Apparatus for comparing the relative power of the muscles in the hind limbs of a rabbit, without dissection.

The recovery in the galvanic response in those animals with crushed or cut and sutured nerves is closely connected with the regeneration of some of the nerve fibers to the stage of union with muscle fibers, because such recovery was shown to be accompanied by reflex control over the muscles. This was determined by holding the rabbit by the ears and exerting sudden upward pressure against the hind feet. In the case of recovery, the animal would offer resistance against this pressure.

There was a very distinct difference in the rate of recovery of both "reflex resistance" and power of galvanic response between denervation produced by crushing the nerve and denervation caused by cutting. In spite of the fact that the cut nerves were immediately joined by suture, the rabbits in which the nerve was crushed almost invariably recovered about two months earlier. Howell and Huber,⁹ in two experiments in which they crushed the nerve on one side and cut and sutured the nerve on the other side, found at the end of twenty-one days that the return of irritability was slightly better on the side on which the nerve had been crushed. They attributed the difference to a better coaptation of fibers.

Our observations indicate that coaptation of the nerve fibers is essential to rapid recovery. Moreover, some of our experiments seem to show that coaptation is essential to complete recovery for, whereas the rabbits with crushed nerves regain full power within a few months, those with cut and sutured nerves recover very slowly even after the time when some of the nerve fibers have become united with muscle fibers. In the time limit of our observations, many of the muscles had not regained the full power which they possessed before denervation (Fig. 2).

Such coaptation as occurs in a crushed nerve is obviously impossible in a cut nerve because there is not the precise chemiotaxis of peripheral over central nerve fibers. This is shown by the groping about of the central fibers, some growing into connective tissue and never succeeding in making connection with muscle fibers, while others find old sheaths, perhaps not their own. Some divide into branches which may eventually reach muscle and thus make up for those which have gone astray.

Again we wish to emphasize the fact that denervated muscle is not a muscle at rest. It is undergoing abnormal changes, of which fibrillation is perhaps only one. Such changes are probably the cause of muscle atrophy, for Langley and Itagaki¹⁰ have shown that

there is an increase in the rate of breakdown of the muscle substance.

We have examined the denervated muscles in three rabbits before and after massage periods ranging from five to twenty minutes (the skin always protected the muscle while it was being treated). There was no apparent reduction in the fibrillation. A similar study of fibrillation before and after galvanic stimulation in six rabbits has shown in no instance anything better than a transient reduction.

In the light of our present researches, we believe that massage in denervated muscle is futile. Galvanic treatment likewise appears to produce no beneficial effect.

SUMMARY

The sciatic or tibial nerve was cut or crushed on both sides of 123 rabbits. The denervated muscles on the right side were either massaged (eighty-six cases) or else stimulated by galvanic shocks (thirty-seven cases), daily.

Union of the cut nerve was prevented in forty-one animals, and in the others it was favored by suture or by crushing instead of cutting.

The right and left muscle groups were compared from every ten to fourteen days by a determination of their power to do work when stimulated by super-maximal galvanic shocks while the animals were under the influence of ether.

Neither massage nor galvanic stimulation prevented the loss in galvanic response which normally develops a few days after denervation. Treatment likewise did not appear to cause a more rapid recovery of the muscle when the nerves were permitted to grow down

to the muscle fibers. Galvanic response and voluntary function in the denervated muscle returned much earlier in crushed nerve cases than in cut and sutured cases.

In all of our work we have been unable to demonstrate benefit from massage or galvanic stimulation.

Torpid Ulcers Heal Under Desiccated Normal Horse Serum.—Local treatment with desiccated normal horse serum for ulcers has been described by Dr. A. Amaral in the *Boletim da Sociedade de Medicina de S. Paulo*, 2:83, 1919. All the ulcers in thirteen cases described in detail were on the legs. No antiseptics are used, or grafts; the lesion is merely powdered well with the desiccated serum after it has been aseptically cleansed. The application is repeated every second day at first and then every third day. From six to eleven applications usually answered the purpose. By the next day the ulcer is found bathed in a puriform fluid but the micro-organisms grow less and less numerous, and disappear by the sixth to the tenth application. The smooth, nonretracting scar tissue grows on an average 0.003 mm. at each application.

Fig. 2.—Typical curves obtained by plotting the work done at the optimum load in treated and untreated denervated muscle: solid line, treated muscle group; broken line, control group; arrow indicates day on which muscle was denervated; A, nerves cut and union with the peripheral end prevented by turning the proximal end aside after capping with a rubber tube; treatment, eight minutes massage, daily; B, nerves cut and sutured; treatment, vigorous contractions produced by galvanic shocks every second for ten seconds followed by a rest of ten seconds, the whole being continued for four minutes daily; C, nerves cut and sutured; five minutes' massage, daily; D, nerves crushed; fifteen minutes' massage, daily. The earlier recovery of the crushed nerve case is to be noted.

TORSION OF THE OMENTUM

REPORT OF A CASE AND A BRIEF REVIEW OF
THE LITERATURE

FRANK BENTON BLOCK, M.D.

AND

HERBERT J. DARMSTADTER, M.D.

PHILADELPHIA

History.—Mrs. B. F., aged 36, admitted to the Jewish Hospital, Sept. 4, 1919, complained of pain in the lower part of the chest and in the epigastrium. She gave a history of a similar attack, but not so severe, five weeks previously. This improved in two days, but tenderness in the abdomen had persisted up to the time of admission. The present pain began on August 28, and at first was chiefly in the mid-epigastrium, but later moved down until it was quite low in the abdomen and more severe in the right iliac region. The pain was mild for four days and aching in nature; then it became much more severe, becoming a constant "cramp-like" or "doubling-up" pain. The abdomen was very tender, and any motion of it produced intense pain. The patient had been nauseated throughout the entire illness, but vomiting, expulsive in nature, occurred only once, having been induced by drinking hot water. The patient had been slightly constipated ever since the onset of the illness, and four days before admission she took a bottle of magnesium citrate and some cathartic pills, which caused the bowels to move and also increased her pain.

The patient had had a right inguinal hernia for twenty-two years which frequently descended, was often painful, and at times was difficult to reduce.

Examination.—On admission, the patient had the appearance of being quite ill. She was moderately obese, and her head, neck and chest presented nothing of significance. The abdomen was tender all over, but especially tender in the right lower quadrant. There was considerable rigidity of the muscles on the right side, preventing the palpation of any mass. A diagnosis of acute appendicitis was made, and the patient was operated on immediately.

Operation and Result.—The peritoneal cavity was opened through a right rectus incision. A little serosanguineous fluid escaped, and at the edge of the incision a greatly swollen mass of gangrenous omentum appeared. The omentum was found to be fixed by its distal extremity to the edge of the internal inguinal ring, and a considerable portion of it had been strangulated between the two points of torsion. The lower twist was just above the internal ring, where the omentum had been twisted into a cord not more than one-eighth inch in diameter. The portion of the omentum below this twist was healthy, probably having received a blood supply from adhesions. The upper twist had a thickness of about three fingers, and when unwound, was found to have undergone five and one-half complete turns. The gangrenous portion was ligated and removed, and a normal appendix was also removed. The uterus was found to be the seat of multiple fibroid tumors, but on account of the poor condition of the patient, these were not disturbed. There was a hernial sac on the right side, but this was empty at the time of operation. The patent internal inguinal ring was closed by suture from within the abdomen. The incision was closed without drainage. Convalescence was uneventful, and the patient obtained a complete recovery.

REVIEW OF LITERATURE

Since torsion of the omentum was first recognized by Oberst in 1882, new cases have been continually reported, so that in 1915 Bookman¹ was able to enumerate 131 cases in the literature, while an estimate of unrecorded or unrecognized cases would make the number much higher. The condition is therefore uncommon rather than rare, and not so interesting as a curiosity as it is from the standpoint of diagnostic

significance. Richardson has defined torsion as a twisting of the omentum on itself, causing sufficient obstruction of the blood supply to cause strangulation. In general, the condition is more frequent in males, the ratio of preponderance being 3 to 1 (Corner and Pinches²), while F. D. Smythe³ says that it is extremely rare in females. It usually occurs in middle aged persons, and its almost invariable association with hernia is a fact important both in etiology and in diagnosis.

The causation of torsion of the omentum is not clear. Some abnormal fixation of the omentum seems to be the universal and predisposing factor. Such a fixation is most frequent in the sac of a hernia, although all intra-abdominal adhesions are possible causes. The two fixed points of the omentum are poles between which the structure is swung (to use an apt comparison of Bookman's) in a manner similar to a hammock. Added to this static condition there must also be an active extrinsic mechanical element bringing about the torsion, since the omentum of itself is not motile. This active element is commonly believed to be the peristaltic action of the intestine. The normally attached omentum, being fixed at only one pole, is easily twisted by every peristaltic wave, and is equally free to untwist. The omentum that is fixed at two extremities, however, when turned about by violent peristaltic action is turned between two zones of torsion. Such a condition must necessarily cause the previously loosely hanging structure to be shortened and tightened between its points of fixation, thus itself impeding its unraveling. It is probably such a shortening and tightening of this band of tissue that prevents the structure (which under normal conditions can easily untwist) from falling back again into its normal position.

The pathologic changes occurring in the twisted omentum are those of strangulation, i. e., anemia or congestion with stasis terminating in gangrene. Infection is rare and is usually hematogenous. In addition, the transverse colon may be caught in the torsion and undergo similar changes, with symptoms of intestinal obstruction. The symptoms in any case will depend on the nature of the torsion; the most complete classification of the different types that may be found has been made by Payr:

1. Torsion without coexisting hernia:
 - (a) Of the omentum only.
 - (b) Of the omentum plus adhering viscera.
2. Torsion with coexisting hernia:
 - (a) Of the intra-abdominal portion only.
 - (b) Of the hernial portion only.
 - (c) Complicated cases:
 - (1) Involving both portions.
 - (2) Either type, associated with retrograde incarceration.

Corner and Pinches give a somewhat simpler division into:

1. Torsion purely abdominal, with no hernia present.
2. Torsion purely hernial. This is the type commonly not recognized as torsion, but diagnosed as strangulated omental hernia.
3. Abdominal torsion complicating a hernia. This is by far the largest group, and is the type usually referred to as torsion of the omentum.

In a condition of such a variable nature the symptomatology must be necessarily multiform. This is even more evident when we consider the complex nature of

1. Bookman: Ann. Surg. 61: 730, 1915; Am. J. Surg. 29: 394, 1915.

2. Corner and Pinches: Am. J. M. Sc. 130: 314, 1905.
3. Smythe, F. D.: Surg., Gynec. & Obst. 3: 531, 1906.

the mechanical factors. Bookman thinks that the symptoms are produced chiefly by the interference with the omental blood supply. It seems most probable, however, that the traction of the tightened band of omentum on the stomach, the transverse colon and their peritoneal attachments is the all-important factor in symptomatology. Pain is the first symptom to appear, usually the most conspicuous, and the only one constantly present. The pain is often sudden in onset, usually abdominal, and frequently referred to McBurney's point, although occasionally referred to the hernia. Corner and Pinches state that there is usually no history of previous illness referable to torsion, although sixteen cases are cited in which previous abdominal symptoms, chiefly pain, were continuous for several weeks. They mention others in which there were histories of recurrent attacks of pain over periods up to nine years. As many as ten complete twists have been found, probably each attack of pain representing an increment of torsion before the final straw brings the patient to operation. Thus, Hartwell⁴ reports a case giving a fairly typical history of gastric ulcer lasting many years in which operation revealed a twisted omentum attached to the healthy wall of the stomach. Hale⁵ reports a case with a similar attack twenty years previously. In Bookman's case there were indefinite cramplike pains for four months, while in our case there was a history of an acute attack followed by a subacute hiatus of five weeks before the final attack.

The pain is usually of an aching or pulling character, and cramps may be present if there is an attendant ileus. Vomiting, according to Corner and Pinches, is present in one third of the cases, although Bookman believes it is present in nearly one half. Usually the vomiting is frequent and violent; occasionally it is blood stained, although nausea without vomiting may occur. If torsion or knuckling of the intestine occurs, the symptoms of mechanical obstruction supervene. The condition of the bowels is variable. They are usually open, but constipation or even obstipation may occur; blood and mucus may appear in the stool if there is obstruction. The temperature is usually slightly elevated, and there is also a moderate acceleration of the pulse. Some rigidity of the abdomen occurs in well developed cases, but the most significant physical sign is the presence of an abdominal mass, especially when associated with a hernia. Mild leukocytosis, with an increase in the polymorphonuclear elements, is usually present.

The foregoing, in addition to a brief study of the literature of the subject, will indicate how difficult the differential diagnosis may be in these cases. The very infrequency of torsion seldom brings it to the mind of the diagnostician as a possibility. It is most frequently mistaken for appendicitis, since that is the most common surgical intra-abdominal condition and is itself often of variable symptomatology. Volvulus is also commonly diagnosed in this condition, and may actually be associated, as previously indicated. Torsion within the sac of a hernia is always diagnosed as ordinary strangulation, nor is the differentiation of any importance.

F. D. Smythe has tabulated the differential points between torsion and appendicitis. These, however, in the main, are purely relative, and while of general academic interest, they are of little value in the

individual case. They indicate only an indefinite probability in diagnosis; but the rarity of torsion makes the probability of its presence infinitely less than that of appendicitis. The more rapid pulse, the lower temperature and leukocytosis, and the less marked septic symptoms, which are usually present in torsion, as well as the possibility of palpating or percussing an abdominal mass, are the most significant of the facts that the patient presents.

A feature in the histories of a number of cases presented in the literature, which seems to us to be of some diagnostic importance, is the nature of the onset. There is a progressive augmentation of symptoms by a series of sharp steps or jumps with intervals of varying length. Such a history is very suggestive of a mechanical disturbance with successive increments, in contrast to the steady and rather smoother continuous aggravation of symptoms in a mounting inflammatory condition. However, from a practical standpoint, there is only one thing that can give the diagnosis of omental torsion any degree of surety, namely, the coexistence of a hernia with the sudden appearance of an abdominal mass. Bookman's correct preoperative diagnosis was based on such a finding; without it a diagnosis is probably impossible. Corner and Pinches hypothesize a type of history, leading to an inferential diagnosis: a man of middle age with an inguinal hernia giving rise to symptoms suggestive in a general way of subacute intestinal obstruction. Examination reveals a painful or irreducible hernia, either incarcerated or strangulated, with a tumor, either in the scrotum or in the abdomen.

The treatment is, of course, operative. Unless there is delay, the condition is not likely to be a severe one, and the operation is technically easy; and it seems to be generally agreed that, in uncomplicated cases, the mortality is almost nil.⁶

CESAREAN SECTION UNDER PROCAIN ANESTHESIA *

J. MORRIS SLEMONS, M.D.

NEW HAVEN, CONN.

AND

J. MURRAY JOHNSON, M.D.

BRIDGEPORT, CONN.

The choice of an anesthetic for cesarean section, always debatable, becomes more difficult in the presence of either cardiac or renal complications; and, if both exist, the problem is indeed a vexing one. Although pregnancy should carry with it some degree of immunity against the toxic effects of chloroform—which is doubtful—certainly its administration to any one suffering from a cardiac lesion would be very dangerous. Similarly, the administration of ether to a patient with pulmonary edema would be hazardous; in such cases even nitrous oxid anesthesia has been followed by pneumonia.

The respiratory distress accompanying decompensated cardiac lesions generally requires that the patient sit up, though confined to bed, and in this position the employment of general anesthesia becomes awkward

at least. Toward the successful treatment of such patients, in urgent need of relief from the strain of pregnancy, no contribution could be more helpful than satisfactory local anesthesia, permitting a safe and speedy evacuation of the uterus. To be satisfactory the anesthesia must permit the patient to retain a posture both comfortable for herself and not unfavorable to the conduct of the operation. For the mother it must provide a greater factor of safety than does general anesthesia. And it must not deter the establishment of respiration in the new-born.

Recently in a case of broken cardiac compensation at the eighth month of pregnancy with pulmonary edema and increasing albuminuria, the method of anesthesia employed for the performance of cesarean section was put to a severe test; and procain met the requirements just enumerated satisfactorily. On the basis of a single case, ordinarily, we should be reluctant to predict how wide the field of application of a method would prove to be; but since we find that Dr. J. Clarence Webster¹ of Chicago announced its usefulness in 1915, and his opinion was confirmed by the experience of Dr. Hugh H. Trout² of Roanoke, we are convinced that our result was not exceptional. The former gynecologist employed it with excellent results in fourteen cases; the latter, among eighteen cases representing various obstetric complications, encountered three maternal deaths from eclampsia and eleven fetal deaths, the cause of which he does not discuss.

REPORT OF CASE

History.—The case which is the subject of this report was that of a young primiparous woman with mitral stenosis and insufficiency decompensated at the eighth month of gestation.

Jan. 3, 1920, she entered the hospital and found temporary improvement from the conservative treatment usually followed in such cases. Ten days later, pulmonary symptoms developed, and on January 15 her distress and her own appreciation of the seriousness of the illness was such that she readily consented to whatever therapeutic measures offered most for her recovery.

At the time she breathed comfortably only when propped upright in bed, and was coughing up a seromucous fluid tinged with blood. General anasarca had developed; the most extensive edema was that affecting the lower extremities and the vulva. The legs, swollen to the utmost, could not be brought together, and were placed comfortably only when abducted about 45 degrees. Each labium majus was distended with at least 300 c.c. of fluid. Through the chest walls, back and front, moist râles were audible everywhere. The area of cardiac dulness was increased; a loud systolic murmur was heard over the whole precardiac area as well as in the axilla; the second aortic sound was accentuated. The irregular pulse was counted between 120 and 140 to the minute; the respirations were 36. The temperature was 99.5 F. The urine, heavily loaded with albumin, contained numerous hyaline and granular casts.

The abdominal wall was edematous, and there were signs of fluid in the peritoneal cavity. The fundus of the uterus was five finger breadths above the umbilicus. The fetus was lying transversely with the head to the left, the small parts in front; the fetal heart, 35 to one-quarter minute, was difficult to distinguish from the maternal pulse. The position of the round ligaments indicated that the placenta was attached to the posterior surface of the uterus.

The clinical problem that the patient presented required an immediate solution, and one logical line of treatment without alternative was open to trial. Since

the spontaneous onset of premature labor, which frequently brings relief, had not occurred, in this instance the pregnancy must be terminated by one of the rapid artificial methods. The vaginal route was out of the question, for in the first place the patient could not lie down without serious embarrassment to both respiratory and cardiac activity; and in the second place, edema of the birth canal precluded the requisite exposure for vaginal hysterotomy. Thus, with laparotomy the remaining route by which to evacuate the uterus, another obstacle was encountered in the risk of its performance under general anesthesia; consequently, local anesthesia was chosen. In the conduct of the operation the steps taken, the phenomena observed and the reaction of the patient will be treated more fully than usual; these technical details have an interest beyond this particular complication of pregnancy, and their description may prove useful to those who adopt the procedure, whatever the type of case.

Operation and Result.—Preliminarily, a half-grain of morphin and a hundredth of atropin were administered hypodermically. Then the patient was placed on the table comfortably in a half-sitting posture supported by pillows. The bladder was emptied by catheterization and the site of the operation prepared in accord with the usual tincture of iodin technic. One c.c. of pituitary extract was administered in the thigh as the operation began.

In the median line, from umbilicus to symphysis, the skin was infiltrated with procain solution, 1:400, to which epinephrin had been added in the proportion of 3 drops of epinephrin to each ounce of procain solution. For cutaneous anesthesia, approximately 30 c.c. of the solution were required, and that sufficed not only during the division of the skin but also of the subcutaneous fat, more than an inch in thickness. As the continuance of the incision caused discomfort, about 20 c.c. of the procain solution were used to infiltrate the fascial layer. Probably the position of the incision, directly in the midline, accounted for the fact that special treatment of the parietal peritoneum was not required; this structure may have been reached by the injection of the anesthetic into the fascia.

After the peritoneal cavity was opened, several hundred cubic centimeters of ascitic fluid were expelled, and loops of small intestine floated in front of the uterus into the upper angle of the wound. These were held back by abdominal pads. The uterus was not delivered through the abdominal incision. Without procain infiltration that portion of the organ which appeared was tested with regard to sensitivity and, as the patient was unable to detect when the knife was in use, after the membranes were exposed, the uterine incision was prolonged with bandage scissors until approximately 15 cm. in length. During this procedure the membranes ruptured and a fetal hand came into view. The fetus was delivered through the aperture in the uterine and abdominal walls by the method usually followed in breech extraction. Careful delivery of the arms, one at a time, and good flexion of the head simplifies the extraction and renders less likely the prolongation of the uterine incision with a ragged tear. The patient made no complaint after the abdominal fascia became anesthetized, was not aware that the fetus was being delivered, and subsequently, except for questions regarding the likely duration of the operation, made no comment.

The loss of blood was not excessive, probably not greater than 400 c.c. After the placenta was removed, the uterine cavity was wiped out with large gauze sponges to remove fragments of the membranes, if left behind, and also to remove blood clots. The internal os, almost closed, was not disturbed, for the uterus had retracted firmly, bleeding had nearly ceased, and we preferred to save time and run no unnecessary risk of causing pain.

The uterine wound was closed with two tiers of catgut sutures. The placing of the deeper interrupted sutures was awkward because the uterine incision retracted to a lower level than the abdominal incision; this difficulty was over-

1. Webster, J. C.: A Series of Abdominal Cesarean Sections Performed Under Local Anaesthesia, *Surg., Gynec. & Obst.* 20: 221 (Feb.) 1915.

2. Trout, H. H.: Cesarean Section Under Local Anaesthesia, *Surg., Gynec. & Obst.* 27: 95 (July) 1918.

come by using the sutures already in place for upward traction. The upper continuous suture approximated the peritoneal edges of the uterine wound. The abdominal wall was sutured in layers without further use of procain. The peritoneum was closed with a continuous catgut suture, and similarly the muscle edges were brought together. The fascia was united with interrupted catgut; the skin and subcutaneous tissue with interrupted silkworm gut. The post-operative convalescence of the mother was afebrile and without untoward complication.

COMMENT

We can confirm Heaney's observation³ that resuscitation of the new-born requires less arduous measures after cesarean section under procain than under general anesthesia. In this instance the infant began to breathe immediately after its removal from the uterus. It weighed 2,000 gm (about 4½ pounds) and measured 42 cm. (16½ inches) in length.

In this case the successful local anesthesia, we believe, must take into account two facts, namely, the initial administration of morphin and the cooperative attitude of the patient. To the former we ascribe the complete control of coughing during the operation—a complication from which we had expected considerable annoyance. It is pertinent that the patient expressed great relief as soon as the uterus was emptied. A less cooperative subject, we can readily understand, would make the employment of local anesthesia impossible.

Certain features of our technic, differing slightly from that described by Webster and by Trout, probably served to spare the patient no little pain. The method employed here was the one we follow as a routine in the performance of cesarean section, and we were not aware that it differed from the technic of others until the papers in question were recently consulted. Thus, the grasping of the lower uterine segment, which Webster found to be a painful maneuver because it placed the ligaments under tension, was unnecessary in our case, for the degree of hemorrhage was not extraordinary.

The delivery of the uterus through the abdominal incision, which Trout described as a crucial step in the operation and the cause of severe pain, is rarely advisable even with general anesthesia. The procedure requires a longer abdominal incision than otherwise, renders more difficult the control of the intestine, and tends to increase the likelihood of infection. If this step in the operation under local anesthesia is omitted, the patient is spared at two points, namely, when the uterus is delivered and when the fetus is extracted. If it lies within the peritoneal cavity, traction on the uterus beyond a given degree is prohibited by the opposition of the abdominal wall, and the ligaments are not stretched.

In general, we agree with Webster and endorse his recommendation of procain whenever a general anesthetic would be unsafe. The solution he used was twice the strength of the one which gave us perfectly satisfactory conditions for an uninterrupted operation. We learn also from reports of its use in general surgery that a 0.5 per cent. solution has been employed without fear of toxic effects even when 200 c.c. were required. Since in that case the subjects were not suffering from cardiac lesions, they are scarcely comparable with our patient, and probably no mistake was made in limiting as far as possible the quantity of procain she received.

If the introduction of this method has any unfavorable results, probably they will be in the nature of extending too far the indications for cesarean section, namely, to cases in which the termination of pregnancy should be secured by the less radical methods for inducing the onset of labor. Therefore, it is important to emphasize the fact that the proper treatment of obstetric complications must not be confused with the question of anesthesia. The former problem must be solved in the light of sound teaching which will contrast the ultimate results obtained, on the one hand, by recourse to cesarean section and, on the other hand, by the use of more conservative procedures. The latter question requires an answer when a frank indication for laparotomy exists and the choice lies between general and local anesthesia. In these circumstances, if local anesthesia is preferable, procain may be employed with ease and confidence. To the mother it offers the requisite safety; and it has less influence toward prolonging the initial period of apnea in the new-born than has ether, nitrous oxid or chloroform.

OBSERVATIONS ON A GREEN-PRODUCING COCCUS FROM THE BRAIN IN A CASE OF ENCEPHALITIS*

S. JOHN HOUSE, M.D.

CHICAGO

I wish to report the results of the bacteriologic examination in a case of encephalitis, diagnosed clinically as encephalitis lethargica.

The case was that of a woman, aged 70, who entered the Cook County Hospital, service of Dr. J. A. Wolfer, March 5, 1919, with impaired mentality, apparently complete loss of memory, and a broken forearm. The present illness was said to have come on suddenly one morning three weeks previously with dizziness. Following this, came mental changes that grew progressively worse. The forearm was broken while preparing her for the trip to the hospital. In the hospital, in addition to these changes, arteriosclerosis was found with increased knee jerk. She lived twelve days in the hospital. There was little or no fever (axillary) until the eighth day, when the temperature rose to 100 F., and also a few hours before death, when there was a sudden rise to 105 F. The respirations ranged between 19 and 22, rising to 38 five hours and dropping to 12 one hour before death. The pulse was about 80 most of the time, increasing in proportion to the temperature. She had no control over the bladder. She slept a great deal of the time, and when not sleeping was stuporous and talked at random. Nothing abnormal was found in the urine except a few white cells on one occasion. The white blood cell count on three examinations at two-day intervals was 8,800, 9,400 and 12,000. No Wassermann, Lange or Nonne tests were made. The duration of illness was five weeks.

Anatomic Diagnosis (Dr. E. R. LeCount).—Encephalitis (lethargic type?); congestion and edema of the leptomeninges; hemorrhages in the trachea and lungs; hyperplasia of the tracheobronchial lymph glands; foramen magnum pressure furrow of the brain stem; marked general anemia; Colles' fracture of the left arm; petechial hemorrhages of the lining of the stomach, trigon and rectum; senile arteriosclerosis; chronic diffuse nephritis; atrophy of the cerebral cortex; fibrous perivascular leptomeningitis with scars; external fibrous pachymeningitis.

Sections for microscopic study were taken from cortex of frontal and parietal lobes, lenticular nucleus and internal capsule, thalamus and hypothalamus, cerebral peduncles, pons,

3. Heaney, quoted by Webster (Note 1).

* From the John McCormick Institute for Infectious Diseases.

and medulla, and stained by the toluidin blue, Gram-Weigert, and hematoxylin-eosin methods.

An encephalitis was present, characterized in the cortex by an increase in glia cells, neurophagia, a shrinkage of the nerve cells in their lacunae, and a marked reticulation of neuroglia tissue. These changes were present in other sections also but to a less marked degree. There was a small amount of perivascular infiltration in some sections. Many of the small venous channels were greatly congested; no hemorrhages or typical plasma cells were seen. There was no evidence anywhere of thrombosis of the cerebral vessels.

In the sections stained by the Gram-Weigert method a few large diplococci and ovoid forms, similar in size and shape to those isolated and studied in pure culture, were seen. There was no regularity in their association with the pathologic changes, as they occurred both in the interstitial tissue and in relation to the cells showing neuronophagia.

Material was taken from the brain for cultures eleven hours after death. This material was obtained by means of sterile capillary pipets which were plunged into the brain at places seared by a red-hot spatula. The sites selected for this were the insula, the cerebral peduncle (about 0.5 to 1 cm. proximal to the pons), and along the inferior lateral border of the temporal lobe. The direction and depth of insertion of the pipets were gaged by sections of a brain hardened in formaldehyd. Then by a few short jabbing motions, with suction at the same time, brain material was drawn into the pipettes and transferred to tubes of melted agar (10 c.c.), kept at 46 C., to which goat blood had been added (10 drops to the tube). The material was emulsified against the sides of the tubes, appropriate dilutions made and plates poured in the usual way. These were incubated for twenty-four hours and studied. A diplococcus developed in pure culture. Not one of the uninoculated plates yielded any growth.

The cerebrospinal fluid and heart blood obtained post-mortem were sterile.

The diplococcus stains by Gram's method: The individual cocci vary in size from about 0.25 to 0.75 micron in diameter, the greatest variation being seen in the short chains which contain from four to eight elements. The diplococcal forms, although similar in shape, differ markedly in size. There are also a few large ovoid forms, 0.75 to 1.25 microns in diameter, which occur singly. All these variations are to be found in a twenty-four hour blood-agar culture.

On blood-agar plates, after twenty-four hours' incubation, pin-point colonies are formed surrounded by a 0.5 mm. greenish zone; the surface colonies are larger, 0.5 to 1 mm. in diameter, greenish and have a greenish zone about them; they are round, moist, and slightly convex. After seventy-two hours there is a small amount of true hemolysis around the colonies. In plain broth a smooth cloudy suspension is formed with some fine white sediment which is readily diffusible. On plain agar, a moderate growth occurs which is moist and slightly opaque to reflected light. On blood serum, the organism grows rapidly. Litmus milk is made slightly acid. Using a 1 per cent. solution of the various sugars in sheep-serum water, with litmus as the indicator, lactose, mannite, salicin, dextrose, and saccharose were fermented; inulin was not. The final readings were made after seventy-two hours.

Rabbits and guinea-pigs were injected by various routes, including the intracerebral, with a thick suspension of twenty-four hour cultures of the diplococcus recovered from the brain, but all remained well except one rabbit that died sixteen days after the injection, apparently from some other cause.

Normal rabbits were injected intravenously at weekly intervals with suspensions of this organism, heated at 56 C. for thirty minutes. The suspensions were made from blood-agar slants, the initial dose being one slant. After repeated injections, serum was drawn and its agglutinins and opsonins studied. In both the agglutination and opsonic tests, twenty-four hour dextrose broth cultures were used with normal rabbit serum and salt solution controls. The agglutination mixtures were incubated at 37 C. for two hours, placed at room temperature for eighteen, at which time the final readings were made. In the opsonic tests, fresh normal human leukocytes were used, and the final mixtures (diluted serum,

leukocytes and dextrose broth suspension) were incubated at 37 C. for thirty minutes, smears made on slides and the point of opsonic extinction determined.

The results shown in the table indicate that immunologically the coccus isolated is distinct from similar green-producing cocci from poliomyelitis, influenza and other sources.

It is of special interest that von Wiesner,¹ the only observer that so far as I know has reported the results of bacteriologic studies of cases of epidemic encephalitis, recovered a gram-positive diplococcus from the brain of every case which he examined (he does not say how many). He does not state that he found the organism in the microscopic preparations.

It is to be noted that the type of changes in this brain are essentially the same as those described by Bassoe and Hassin² in their report of three cases, the chief difference being one of degree. It is also interesting to note that a careful review of the reported cases of epidemic (lethargic) encephalitis has failed to reveal any uniformity in the degree in which these changes may occur in the various portions of the cen-

REACTIONS OF SERUM OF RABBIT INJECTED WITH
ENCEPHALITIC COCCUS

With normal rabbit serum the encephalitic coccus was agglutinated at a dilution of 20 only; practically no phagocytosis.

tral nervous system; nor is there any definite grouping of pathologic changes that can be described as occurring in all of the reported cases.

The fact that the heart blood and cerebrospinal fluid were sterile indicates that the infection of the brain was not agonal.

The diplococcus isolated is a large green-producing streptococcus, similar in many respects to other green-producing cocci, but apparently different in its immunologic reactions.

Hospital Ventilation.—A highly successful hospital superintendent attributes a great amount of his success to the fact that he has made a study of, and has been able to recommend and put into operation, a plan for the systematic ventilation of hospitals of which he has had charge, and this arrangement has been so satisfactory that doctors give his hospital preference wherever possible. He has found, he says, that the condition of the air has more to do with the health of the patients than most of us have any idea of, and that instead of mechanical equipment rightly installed proving an expensive proposition, it is in reality a most economical method.—C. A. Eddy: *Hospital Management* 9:45 (Jan.) 1920.

Clinical Notes, Suggestions, and New Instruments

A SCREW TRACTOR FOR USE WITH THOMAS' SPLINT

R. M. YERGASON, M.D., HARTFORD, CONN.

Associate Orthopedic Surgeon, St. Francis' Hospital

The Thomas splint and its recent modification, the so-called new model or high-bridge splint, require suspension in order to keep the ring, or its equivalent, beneath and against the tuber ischii as the point of countertraction. The entire extremity and splint are balanced to maintain this suspension by two or more weights, aggregating, let us say, 20 pounds. For the sake of clarity I shall speak of this as the upper, or balance, weight. If we desire to apply 15 pounds of traction to the extremity by means of weights and pulleys, this weight is added to that of the splint and leg and must be compensated by an equal amount added to the balance weight above.

Fig. 1.—Details of tractor, viewed from above.

Should this be carried out we should have the weight of the extremity and splint plus 15 pounds, balanced by 35 pounds as an upper weight. This gives a total of close to 70 pounds to be carried by the Balkan frame. All this is heavy and a nuisance, and the patient justly feels that there is a great weight hanging over him. If a traveler is used to enable the patient to move up and down the bed, such a weight is out of the question. It therefore becomes necessary to do away with weight and pulley traction when using suspended splints.

To accomplish this desirable end, several tractors depending on a screw have been devised. Some of these lack a means of determining the amount of pull; others are heavy, clumsy or difficult to apply.

My purpose here is to describe a tractor which, in addition to eliminating some of these difficulties, is adaptable to various conditions and different splints.

The tractor consists of the following main parts, each of which I shall later describe somewhat in detail: A horizontal cross-piece (A) corresponding to the wooden block of the old Buck's extension; a hook-shaped piece (B) which furnishes a seat for both the cross-piece and the head of the screw; a screw (C), provided with a wing nut (D), by means of which the traction is applied; a carrier (E) for attaching the tractor to a Thomas splint; a spring (F), bearing a scale (G) for the purpose of measuring the amount of traction,

and a transverse rod (H) carried by the bearing (I) for the purpose of preventing rotation out of the horizontal plane.

The cross-piece (A), corresponding to and taking the place of the foot block of the old Buck's extension apparatus, consists of a piece of $\frac{3}{32}$ inch sheet iron (A-A), 5 by $1\frac{1}{8}$ inches, bent on itself lengthwise, and thus furnishing a mount for two small brass pulley wheels (b-b), which measure $\frac{5}{8}$ inch in diameter by $\frac{1}{4}$ inch thick. At its central part the cross-

Fig. 2.—Details of tractor, side view.

piece is thickened by means of a second piece of $\frac{3}{32}$ inch sheet iron (c), $\frac{3}{4}$ inch wide, soldered to A.

The second part or hook-shaped piece (B) is made of $\frac{3}{32}$ inch sheet iron. At one end (proximal) it is bent into two hooks (d, d) which serve as a seat into which the cross-piece (A) slips easily and is there firmly held. At the other (distal) end, this piece (B) is bent up at a right angle where a $\frac{3}{8}$ inch hole allows the bolt (C) to be slipped into place. The top of this up-standing portion is rounded from side to side.

The bolt (C) is a standard $\frac{5}{16}$ inch carriage bolt 6 inches long, threaded all the way down, and carrying the wing nut (D).

The carrier (E) is of $\frac{3}{32}$ inch sheet iron. Its lower portion is quite wide (3 inches), and is so bent as to grasp the U-shaped bend at the end of the Thomas splint (J), to which it is clamped by means of a small bolt and wing nut (L). The upper part carries the bolt (C) through a sleeve of $\frac{3}{4}$ inch tubing (e), which is brazed on. The bolt slips loosely through this sleeve and is not threaded into it in any way. Above the sleeve the carrier (E) is rounded from side to side. The compression spring (F) slips easily over the bolt. Attached to the spring by means of one link of chain is a small copper tag or scale (G), the graduations of which denote the amount of traction in pounds. The washers (f-f) at each end of the spring serve as points between which the length of the spring may be conveniently measured.

Across the hook-shaped piece (B) is a saddle shaped bearing of sheet iron (I); through the two holes of which a $\frac{1}{4}$ inch rod 8 inches long (H) is passed and held in place by two cotter pins (g-g). This rod rests on the side bars of the Thomas splint (K).

Fig. 3.—Manner in which tractor is attached to the extremity.

To attach the tractor to the extremity, wire triangles or D-rings are fastened to the adhesive plaster stickers. To one of these the end of a piece of picture wire is made fast. The other end of the wire passes through the D-ring of the opposite sticker and is attached to itself by means of a small jamb cut from a scrap of sheet iron (Fig. 3). The tight or free loop of the picture wire is laid over the two pulleys of the tractor, and all slack is taken up by means of the jamb. Traction may now be applied by means of the wing nut (D), the amount of the compression of the spring being read on the scale.

There are great advantages in this method of attachment. Should the adhesive slip or lengthen on one side of the leg, the wire will adjust itself around the pulleys and the result will be a slight lessening of the traction. The pull will remain steady, however, and equal on the two sides, as the cross-piece will not take the oblique position commonly appearing in the foot block of the Buck's extension. The nurse, observing the lessened pull, gives the nut a few turns and all is as before. Further, should the heel pin be used, the picture wire can be measured beforehand, boiled up with the instruments, and applied during the operation. In this case there will be no necessity for disturbing the dressings about the heel pin when the patient has returned to the ward.

As the cross-piece (*A*) is held simply by two hooks between which its reinforcement (*c*) is snugly jambed, it may be slipped out at any time and another style of cross-piece substituted.

The rod (*H*) carried by its saddle (*I*) rests on the side bars of the splint (*K*), thus preventing rotation of the cross-piece. By removing one of the cotter pins (*g*) the rod may be withdrawn and the saddle removed. This is convenient should it become necessary to reverse the tractor and attach it beneath, instead of above, the splint, in which case the saddle may be applied in the inverted position, bringing the rod above the side bars of the splint as before. In this case the holes (*h*) in the saddle are used for the passage of the rod so that the tractor will remain horizontal beneath the splint. By reversing the figured side view of the tractor, its arrangement when beneath the splint will be at once apparent.

The bolt can be slipped out and a longer one, or one of different thread, substituted should this be desirable. In use the bolt may become screwed up to the point where its head is close to the sleeve (*e*) of the carrier. In this event there will be no traction on the extremity, shortening of the spring simply indicating the amount of force with which the bolt head is drawn against the sleeve. This is a small point to guard against in the use of the tractor. Should it occur, all that is necessary is to turn the wing nut back to the end of the bolt and take up the slack of the picture wire by which the tractor is attached to the extremity.

As regards measurement of the traction, any spring of the compression type (in contradistinction to the expansion type) which will slip easily over the bolt may be used. An unknown spring is placed on the tractor, which is attached to the splint, and a spring balance substituted for the extremity of the patient. The blank copper tag is scratched to indicate the length of the spring under varying amounts of traction as shown by the spring balance. The tag is attached to the spring, constituting a scale to indicate the amount of traction on the leg. A spring which is compressed about $\frac{1}{8}$ inch for each 5 pounds and is long enough to indicate 40 or 50 pounds of traction, before being completely pressed together, will be found most convenient.

To use the tractor with the high-bridge splint, the clamp of the tractor may be attached to the lower bar of the strap-iron rectangle at the distal end of the splint (Fig. 5 *M*). More satisfactory than this, however, is to fasten a bar of flat metal (*N*) across the rectangle. This bar should have a hole $\frac{3}{8}$ inch in diameter at its middle point, through which the bolt (*C*) of the tractor is passed. This new bearing does away with the necessity of the clamp and sleeve (*E*), which is removed. The tractor may be attached to the movable leg-piece of the high-bridge splint, in a similar way, by simply boring a hole in the middle of the transverse part of the leg piece.

The whole tractor as described is only 8 inches long. A much shorter form may be had by using a permanent cross-piece, eliminating the cross rod (*H*) and using a shorter bolt (Fig. 4). This makes possible its use with a splint only very slightly longer than the extremity.

Fig. 4.—Short form of tractor.

ADVANTAGES

The advantages of the tractor may be thus summed up: It weighs only a few ounces, yet will produce any desired amount of traction. Although designed for use with the Thomas splint, it may be easily attached to any other metal splint. It is quite short, which economizes space in the length of apparatus, a by no means minor consideration. Various springs may be used, so that very light or extremely heavy traction may be applied.

The compression spring has a distinct advantage over the expansion or spring balance type of tractor, for it occupies less room in the splint the greater the traction, whereas the expansion spring lengthens with greater tension, thereby necessitating a longer splint. The foot-piece with pulleys does away with the obliquity of the old Buck's extension foot-block, and eliminates torn adhesive stickers.

The ease with which the tractor is assembled makes possible the substitution of different parts to meet special or varying conditions. The apparatus is simple and easy of construction. In use at the St. Francis Hospital we have found it satisfactory in every way.

ACUTE HEMORRHAGIC NEPHRITIS SECONDARY TO MIDDLE EAR INFECTION

REPORT OF CASE

JOHN W. SHUMAN, M.D., SIOUX CITY, IOWA

Renal irritation, indicated by albumin, casts and red and white blood cells in the urine, and "focal infection" I have witnessed a number of times; but the case reported here offered the first opportunity to observe an acute renal irritation of such severity, secondary to suppurative otitis media, complicated by mastoiditis and lateral sinusitis, caused by the streptococcus micro-organism, from onset to recovery.

The child was examined, Dec. 2, 1919. About this time a very helpful article by Dr. Lewis Webb Hill¹ appeared in THE JOURNAL, in which were mentioned four cases of nephritis secondary to otitis media.

This case is reported as corroborative evidence of the material presented in that article, and for the aid it may give to those encountering the same or similar pathologic conditions. It emphasizes the fact that renal disturbance is a secondary rather than a primary disturbance.

REPORT OF CASE

A girl (Record No. 1948), aged $3\frac{1}{2}$ years, was admitted, Dec. 2, 1919, to the eye, ear, nose and throat service of Dr. J. B. Naftzger, St. Joseph's Hospital, Sioux City, Iowa, with the diagnosis of suppurative otitis media. The left ear was discharging. The temperature was 100 F., the pulse, 130. Blood examination revealed: white blood cells, 36,200; polymorphonuclear neutrophils, 74 per cent. Mastoid tenderness and "shadowed" cells, demonstrated by the roentgenogram, were present. These findings led to the diagnosis of mastoiditis complicating suppurating otitis media. But the urinalysis by Dr. Mortimer Herzberg (director of the laboratory) complicated things greatly: amount, 5 ounces; bloody; acid; specific gravity, 1.015; albumin present in large amounts. Microscopic examination revealed an enormous number of red blood cells and a number of granular casts.

It was decided at consultation that the renal condition was secondary to the ear infection, and mastoidectomy was performed under nitrous oxid anesthesia administered by Dr. R. M. Waters. The mastoid cells were necrotic. A report of cultures was: "a few isolated diplococci; a few short chains

1. Hill, L. W.: Acute Nephritis in Childhood, J. A. M. A. 73: 1747 (Dec. 6) 1919.

of streptococci; some diphtheroid and staphylococcic micro-organisms."

At the time of operation the lateral sinus was exposed and appeared not to be involved, but the symptoms did not disappear after the operation; in fact, they became more alarming. December 7, five days later, the temperature was 105.4 F., the pulse 140 and white blood cells, 22,500 (polymorphonuclear neutrophils, 82.1 per cent.). The urine (twenty-four hour quantity, 7 ounces) was very bloody and contained albumin +++ and many granular casts. Physical examination was otherwise negative. On account of these conditions it was thought that the lateral sinus was involved, so Dr. R. Q. Rowse ligated the left external jugular and Dr. Naftzger opened and cleared out the sinus which was thrombotic. Following this procedure, the temperature descended by lysis (normal, February 8), the urine changed and became "smoky" four days later, and the albumin was ++ instead of +++. A week later, the albumin was + and January 22 there was only a trace. The same decrease in pathologic evidence was observed in the microscopic findings. Jan. 25, 1920, the patient was discharged from the hospital.

LATER DATA

The urinalysis was negative January 9, and remained so until January 29, at which time the little girl complained of "a hurting" in the urinary bladder region and urinated small amounts frequently. Albumin and a number of red blood and pus cells were found in the voided specimen. That night the mastoid incision, which had healed over, "opened and drained pus." The urine of February 3 was negative except for an occasional red blood cell. This would appear as added evidence to substantiate the belief that the middle ear infection caused the pathologic condition of the kidney.

Frances Building.

THYROTOMY IN REMOVAL OF A SUBGLOTTIC LARYNGEAL EPITHELIOMA

BERTRAM C. DAVIES, M.D., LOS ANGELES

The question of routes in operating for the removal of laryngeal growths is one that cannot be settled by any fixed rule. A decision must be based largely on (1) location and (2) variety of growth.

Obviously a papilloma, located, as it usually is, on the vocal bands in the anterior part of the larynx, occupying the supraglottic region, and being more or less pedunculated, can be snared off by the direct or indirect endolaryngeal route. Other and more serious growths, depending on their location, may be removed by the same route. Occasionally there is an epithelioma that has a reasonably long pedicle, even though it be subglottic, that may be removed by direct laryngoscopy. No general rule applies, however, and specific consideration must be given in each case as to the route of operation.

The case here reported demonstrates, among other things, that some study is necessary at times before any decision can be reached.

REPORT OF CASE

History.—W. B., man, aged 66, bricklayer, seen May 4, 1919, whose father and mother were over 80 years old at death, weighed 170 pounds, and there had been no change in weight during the last two years. He had had the ordinary diseases of childhood. He denied venereal infection. When 21 he had bronchitis, which lasted several years; he was quite ill with abnormal temperature and considerable cough, raising thick mucus. He was unable to work. Recovery had been slow. He had been a heavy smoker for the last twenty-five years. About six months before, he had noticed his voice becoming hoarse and weak. There was no pain or cough and deglutition was normal. There had been gradual increase in hoarseness, which was more marked during the past month and was worse at night or when the patient was tired.

Physical Examination.—The nose and nasopharynx were negative. There was granular pharyngitis. There was marked "hooding" of the epiglottis, but no inflammatory condition. The mucous membrane of the arytenoids was injected

and swollen, with superficial ulceration in the posterior commissure. The false cords were swollen; this swelling, together with the condition of the arytenoids, obliterated all but the anterior third of the true cords. Some injection of the true cords was noted. Examination of the chest gave evidences of healed pulmonary lesions, some emphysema, and fine râles over both apexes. Roentgenoscopy revealed scar tissue rather evenly distributed over both lungs, with a slight increase on the left side. The Wassermann test was negative. The von Pirquet reaction was ++. The blood count was normal; hemoglobin, 85 per cent. A tentative diagnosis of tuberculous laryngitis was made.

Treatment and Course.—The intratracheal use of argyrol, 30 per cent., daily, was prescribed, and tuberculin was given. Smoking was stopped. Phonation was discontinued. Alternating hot and cold packs were employed one-half hour at bedtime.

After four months' treatment the ulceration healed and the laryngeal swelling subsided, the true cords gradually coming into view. This was largely due, no doubt, to interdiction of the use of tobacco and the employment of voice rest.

Under cocaine, 20 per cent., the direct laryngoscope was used and a positive diagnosis of epithelioma was made. The neoplasm was subglottic, lying under the left cord and not having a pedicle; it was white, papillary, and incorporated in the body of the cord for its full length, leaving the edge free. There was no inflammation of the cord or the surrounding tissue.

November 3, thyrotomy was performed under ether anesthesia by the open method.

Some authorities advise preparatory tracheotomy some days previous to this operation, but it was decided to perform the two at one time.

Operation and Result.—A median incision was made from the os hyoideum above to the level of the fourth ring. Careful dissection was then done, exposing the thyroid and cricoid cartilages and tracheal rings. Whenever possible, blood vessels were ligated before cutting. This was not always feasible; but the amount of blood lost did not exceed 2 ounces. When the field of operation was entirely exposed, the second tracheal ring was incised and a No. 4 tracheotomy tube inserted.

At this stage the anesthetist changed his position and administered the ether by means of a saturated pledget held over the opening of the tube.

The attempt was next made to incise the thyroid cartilage, passing a knife through the cricothyroid ligament; but in this particular case, ossification had taken place and bone had replaced cartilage. Several efforts were made with different instruments, keeping in mind the necessity of avoiding injury of the cords; finally separation of the lateral halves was accomplished with a heavy pair of Seiler's turbinal scissors. Even retraction of the lateral halves then gave a good view of the neoplasm, verifying the diagnosis as to the location and probable nature of the growth. At this juncture a gauze pack was introduced into the trachea at the cricoid level to prevent leakage of blood from above, as well as to aid the anesthetist by forcing respiration by way of the tracheotomy tube.

A wide and careful dissection was done, carrying the incision down to the lateral wall of the thyroid and back to the arytenoids, including the cord with the tumor mass, leaving, however, a narrow border of the upper portion of the cord. The tissue below the site of the tumor was dissected and the edge drawn up and sutured to this remaining portion of the cord, thus affording a line of articulation for the right cord. Subsequent events have justified this effort, as the patient's phonation is quite as good as before the operation.

The hemorrhage was very slight, and only three catgut sutures, No. 00, were necessary to produce closure of the tumor site.

The tracheotomy pack was now removed and the halves of the thyroid cartilage were brought together and held by chromicized catgut through the perichondrium and surrounding tissue. The skin was closed with silk worm sutures.

A stiff collar of several layers of adhesive plaster was applied over a dry dressing, immobilizing the thyroid carti-

lage. This collar was reapplied after each dressing until union of the halves was accomplished.

The tracheotomy tube was removed on the fourth day.

The patient made an uneventful recovery, having no respiratory difficulty at any time. The temperature at the highest point was 99.4 F. There was little, if any, postoperative pain and total absence of cough. The treacheotomy wound was closed in three weeks. The patient returned to his regular employment of bricklaying in four weeks.

1113 Los Angeles Investment Building.

A CASE OF IDIOSYNCRASY TO ACETYSALICYLIC ACID

THURMAN D. KITCHIN, M.D., WAKE FOREST, N. C.

The extent to which acetylsalicylic acid (aspirin) is used, both by the profession and the public at large, and the infrequency with which untoward effects result from its use, warrant the report of this case.

REPORT OF CASE

On Thursday, Feb. 5, 1920, an influenza patient was admitted to the College Hospital. The next day he complained of so much pain in his back and head together with general aching, that at noon he was given 5 grains of acetylsalicylic acid. This dose was repeated at 4 o'clock and at 8 o'clock the same day. At 10 o'clock that night there were no untoward effects. The next morning (Saturday) a slight rash was noticed on the face and arms, and although acetylsalicylic acid was suspected, the patient was given another 5-grain dose. In two hours he exhibited a severe form of angioneurotic swelling of the face, especially marked about the eyes. This did not involve the mucous membrane of the mouth and throat. The entire trunk and limbs were covered with an urticaria. The wheals were of irregular shape, and varied in size from one-half inch to more than 2 inches in diameter, and were accompanied with intense itching. This condition lasted all day and did not begin to fade until 11 o'clock that night. By morning it had disappeared.

The patient was a medical student, and with his consent, and purely as an experiment, at this time (Sunday morning) he was given another 5-grain dose of acetylsalicylic acid. In less than an hour the picture described above was exactly reproduced, lasting until the following morning. The patient was then given 2½ grains, and in less than half an hour showed the same results as before, except that this time it lasted thirty-six hours. The patient was now given 1 grain, and in about an hour and a half the same effects resulted, but were less severe and disappeared in about ten hours. It might be added that during all this time the patient received no other drug whatever, and his elimination was apparently excellent.

At no time did the patient show any alarming symptoms, as is usual in such cases. The effect seemed to be entirely limited to the skin manifestations.

COMMENT

There are elements in this case which point either to a cumulative action of the drug or to a condition of anaphylaxis. The fact that so small a dose as 1 grain, given thirty-six hours after a 2½-grain dose, should produce the condition described suggests that either the drug was not eliminated or destroyed in the body as rapidly as is generally thought, or that the first doses rendered the patient hypersensitive to the drug—an anaphylactic reaction.

Rates of Mortality as Related to Conjugal Condition.—The effect of conjugal condition on mortality has often been discussed. The findings of Knibbs, statistician for Australia, are in accord with the usual ideas on the subject: "For males between 20 and 85 years of age the death rate is considerably higher for the 'not-married.' For females the advantage lies with the 'not-married' until the child-bearing period has been passed, after which it lies with the 'married.' The exact age at which the death rates become equal in the case of females is probably about 43 years."

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

PHENACAINE.—Holocaine Hydrochloride.—Ethenyl-Paradiethoxy - Diphenyl - Amidine Hydrochloride.— $\text{CH}_2\text{C}(\text{NC}_6\text{H}_4\text{OC}_2\text{H}_5)_2(\text{NH}_2\text{C}_6\text{H}_4\text{OC}_2\text{H}_5)\cdot\text{HCl}+\text{H}_2\text{O}$.—The hydrochloride of phenetidinyl-acetphenetidin, a basic condensation product of parphenetidin (para-ethoxy-amino-benzene) and acetparphenetidin (phenacetin). Phenacaine was first introduced as holocaine hydrochloride.

Actions and Uses.—Phenacaine is a local anesthetic like cocaine but having the advantage of a quicker effect and an antiseptic action. Five minims of a 1 per cent. solution when instilled into the eye are usually sufficient to cause anesthesia in from one to ten minutes. It is said not to cause the scaliness of the cornea which sometimes results after the use of certain other local anesthetics.

Dosage.—It is applied in a 1 per cent. aqueous solution. Phenacaine is incompatible with alkalis and their carbonates and the usual alkaloidal reagents. Glass vessels should be avoided in preparing the solution, porcelain being used instead.

Phenacaine is prepared by the interaction of molecular proportions of parphenetidin sulphate and acetphenetidin in the presence of phosphorus oxychloride, decomposing the resulting phenacaine sulphate with sodium hydroxide, crystallizing the base from alcohol, neutralizing it with hydrochloric acid, and crystallizing.

Phenacaine forms small, colorless crystals; odorless; faintly bitter and producing transient numbness on the tongue; permanent in the air.

Phenacaine is soluble in about 50 parts of water; freely soluble in alcohol and in chloroform; insoluble in ether. On boiling in glass vessels, the aqueous solution becomes turbid owing to a separation of a small quantity of the free base by the alkali derived from the glass. Phenacaine forms a clear, colorless solution in water, the solution having a neutral or faintly alkaline reaction on litmus.

The aqueous solution of phenacaine yields a white precipitate on the addition of silver nitrate test solution or of ammonia water.

The addition of a few drops of chlorinated soda solution to a saturated, aqueous solution of phenacaine produces a finely divided, flesh-colored precipitate. In a few minutes, this separates as a violet-colored precipitate, and if the mixture be shaken with ether, the ether is colored Burgundy-red.

Dissolve about 0.05 Gm. of phenacaine in 2 Cc. of concentrated hydrochloric acid, boil for two or three minutes, cool and add one drop of potassium dichromate test solution. No ruby-red precipitate is produced (absence of 5 per cent. or more of acetphenetidin or parphenetidin).

Dry about 1 Gm. of phenacaine, accurately weighed, to constant weight at from 100 to 105 C. The loss does not exceed 7 per cent.

Phenacaine dried as above melts at 189 C.

To about 25 Cc. of water and 5 Cc. of ammonia water contained in a separator, add about 0.5 Gm. of phenacaine, accurately weighed, which has been previously dried to constant weight at from 100 to 105 C. Extract the free base by shaking with successive portions of chloroform. (Preserve the solution in the separator for the test for phosphorus compounds given below.) Collect the chloroform solutions in a beaker by passing them through a small funnel holding a pledget of cotton. Evaporate the chloroform and dry the free base at from 100 to 105 C. to constant weight. The weight obtained should be not less than 87.5 or more than 90.5 per cent. of the weight taken.

Purify the base by crystallization from hot alcohol, and after drying to constant weight, determine the melting point. It melts at from 116 to 117 C.

To the solution remaining in the separator, after the original extraction of the base, add an equal volume of concentrated nitric acid and boil for five minutes. Evaporate this solution to about 25 Cc. and add to it 25 Cc. of ammonium molybdate test solution. Keep the mixture at a temperature of about 60 C. for three hours. No yellow precipitate is produced (phosphorus compounds).

Incinerate about 0.5 Gm. of phenacaine accurately weighed. Not more than 0.1 per cent. of ash remains.

Phenacaine-Werner.—A brand of phenacaine complying with the N. N. R. standards.

Manufactured by the Werner Drug and Chemical Co., Cincinnati, O. No U. S. patent or trademark.

SPIRITS AND THE MEDICAL MIND

The linguistic devices by which we distinguish between a specialist in the laws of the behavior of matter, one who deals with the functions of the body, and still another who ministers to the body diseased, indicate that for human ends we must divide what in nature is joined. We call the one man a physicist, the second a physiologist, the third a physician. The names, like the pursuits, all begin alike, for they are but phases of a common nature. So when any doctrines come forward that threaten to overturn the common foundation of science, physicist, physiologist and physician are equally concerned, and with them in these days the psychologist, who shares somewhat of the habit of mind of all three. But so far as the psychologist has a special warrant to consider belief in spirit-agency or in telepathic or other unrecognized forces, he approaches the matter with the clinical sense congenial to the medical mind.

In this mood he is far more interested in noting why people believe in the revelations of mediums, and flock eagerly to listen to tales and to theories that support their inclinations, than he is in any patient analysis of the evidence to see what it really shows. In the larger aspect this is an anthropological interest, for we know that men in all stages of development have been believers in spirit-agency and have brought forward evidence and theory to hold together their beliefs. We know that this ancient world of folk-belief, of superstition, of readiness to think of things in occult terms, survives in all ultimate issues of human existence. Tap the stream where you will and it shows a common expression. No phase of it is more persistent than the medical; people always want health, and will go through amazing procedures to secure it, swallowing potions and theories with equal appetite. One could write a history of the human mind in terms of the cures that people underwent and the reasons offered for the cult. One could start with humors and temperaments, and wind through exorcism, laying on of hands, mesmerism, clairvoyance, homeopathy and Christian science, with any number of side excursions to delay one's progress. Spiritualist

healers who in a trance state prescribe harmless drugs at hurtful prices are by no means obsolete.

But all this is relevant mainly because the type of mind inclining to such cults has in pronounced cases a clinical interest. When we come to mediums who invite a trance-like state to deliver their oracles, like Mrs. Piper, or find that Mrs. Curran can deliver herself of the "Patience Worth" phase of her personality more readily by some slight shunting of the mental gears, or find that Mlle. Smith utilizes a séance room as a stage for her dramatic instincts, we know that there is a psychiatric interest here; and we can the more readily anticipate that a similar or at least congenial trend may be common among their following, who obtain a satisfaction from the belief in the occult. The Freudians (that is, rational Freudians—for despite the common rumor to the contrary, there are such) are ready to see in such expression some compensation for the loss of more real satisfactions, or some converted or perverted outlets for wishes that find a harsh repression in the insistent pressure of a hopelessly complex life. In brief, the will to believe in the supernatural, now so conspicuously resurrected, is a symptom of the stresses and strains to which the minds of men have been put in recent years. The addresses of Sir Oliver Lodge have acted as a respectable mode of relief—that explicit act of confession which Freudians recognize as helpful to ingrowing ailments.

Since all movements take their impress from their leaders, we are particularly concerned with the diagnosis of the spokesmen of the cult. Several hundred years ago, the common or even the educated man who had some real belief in witchcraft or in the journeys of witches through space on brooms, would have been normal enough; but today we should find such belief a ground for mental examination. We should assume that a mind adjusted to the thought-habits of today would have set up a resistance to any such beliefs—assuming any trend toward them—so completely adequate as to reject them without effort. Education is the vaccination that confers immunity; but it does not always take. We are then properly amazed that a mind of superior training, especially in scientific discipline, should subscribe to beliefs on evidence that it is difficult to conceive as convincing to any but a prejudiced will to believe. That kind of predilection when strengthened and systematized, becomes akin to an obsession; it approaches the uncertain borderland in which psychologist and psychiatrist venture together in the hope of bringing order out of chaos. That a peculiarly imaginative man of letters like Maeterlinck should find in the occult an additional outlet for his fancies is not strange; that he should accept square-root-extracting horses as genuine, as men of former days accepted the unicorn as a plausible equine specimen, may indicate a lamentable failing in logic, but

nothing more serious clinically. That Dr. Conan Doyle, though he has long left the medical field for more interesting adventures, should be caught in the same web is in a measure surprising. Yet the conclusion that science does confer an immunity to such tendencies to believe personally engaging conclusions and blind oneself to the irrelevance of the evidence, is not really shaken. The very surprise is a token of the exceptional character of the association of physics or medicine with spirits. For here, too, there is dissociation with a wall rather than a cleft between; the physicist and the physician, though they keep house in the same tenement of clay with the believer in spirits, are not cooperative, though the one borrows utensils and recipes from the other.

In the dissemination of such views, the medical mind has alike an interest and a responsibility. The real illumination of these intricate and elusive relations lies in their clinical aspect; for the clinical sense is a cultivated variety of prospecting among human expressions, and diagnosis is merely an expert form of "sizing up" the sorts and conditions of men that impart variety to an otherwise dull existence. The fact that sanity and sanitation are alike the care of the physician indicates that the medical mind has an important social function. From its point of vantage it sees the ensemble of a forest in what to the wanderers in the jungle of human nature is only a tangle of trees. Beliefs also are symptoms that, placed in their setting, compose into "cases" illuminating and illuminated by collateral findings. In considering the sources and significance of the revival of belief in spirits and the increased tendency to credit varieties of belief and indulge in conclusions reminiscent of earlier stages of mental growth, the medical mind contributes not only an interest associated with its responsibility, but also something in the way of a map to plot the phenomena in an intelligible system.

THE CALCIUM METABOLISM OF INFANTS

Ever since present-day methods of modifying cow's milk for the use of infants have come into vogue, questions pertaining to the preferable proportions of the various milk components have been raised. It is probably no exaggeration to say that one could designate eras in which an undue content of protein, fat or sugar, respectively, in milk was in turn held responsible for various types of infant digestive disturbance or malnutrition. Pediatric progress has made it possible today to control with intelligent dietetic procedures each of the factors just referred to, and their rôle is continually becoming more clearly defined.

The mineral nutrients, especially the indispensable element calcium, likewise have not failed to be included in the controversies of infant nutrition. It will be recalled that cow's milk is decidedly richer in calcium

than is the human mammary secretion, the latter containing only about one-fifth as much per fluid volume. The cereal foods so often fed to infants are decidedly deficient in this element. What, then, represents the optimal intake of lime for the artificially fed infant? Is a considerable departure from this detrimental to health? Obviously, a shortage of an indispensable building stone for the skeletal structure is undesirable; but one can also read of a menace from "too much calcium" for infants. Not only is it argued that a liberal intake of calcium may interfere with the alimentary utilization of fats by inducing an excretion of calcium soaps in the stools, but it has also been asserted that a larger intake of calcium leads to a storage in the body which may have injurious effect.

Here, as is so often the case in the medical sciences, scientific data are needed in place of, or at any rate to supplement, empiric conjecture. Holt and his associates have ascertained the average absorption of calcium by breast-fed infants to approximate 0.06 gm. (calculated as calcium oxid) per kilogram of body weight. This may be assumed likewise to be the requirement of infants receiving modifications of cow's milk. As a matter of fact, the average absorption of calcium oxid by healthy infants taking such diets has recently been found to average 0.09 gm. per kilogram.¹ Since, according to these investigations at the Babies' Hospital, New York, infants taking modifications of cow's milk absorbed on the average only about 45 per cent. of the calcium intake, it is necessary to provide for them a minimal intake of about 0.13 gm. of calcium oxid per kilogram to insure even the low average absorption of breast-fed infants. In general, the data correspond with the earlier calculations of Hoobler,² who estimated the requirement by an infant of 7 kg. at from 0.143 to 0.215 gm. of calcium oxid per kilogram of body weight. A pint of cow's milk furnishes nearly 1 gm. of calcium oxid.

According to the recent findings of Holt, Courtney and Fales, the best absorption of calcium was obtained when the calcium intake bore a definite relation to the fat intake, that is, when the food contained from 0.045 to 0.060 gm. of calcium oxid for every gram of fat, and when at the same time the fat intake was ample, not less than 4 gm. per kilogram. An excessive calcium intake apparently did not increase the calcium absorption, the excess being excreted. When the intake of calcium oxid was very low, less than 0.1 gm. per kilogram, the absorption of calcium oxid was less than the normal calcium requirement of the body. The total absorption of calcium oxid varied in general with the weight of the child; the absorption per kilogram did not vary regularly with either the age or the weight.

1. Holt, L. E.; Courtney, A. M., and Fales, H. L.: Calcium Metabolism of Infants and Young Children, and the Relation of Calcium to Fat Excretion in the Stools, *Am. J. Dis. Child.* **19**: 97 (Feb.) 1920.

2. Hoobler, B. R.: The Rôle of Mineral Salts in the Metabolism of Infants, *Am. J. Dis. Child.* **2**: 107 (Aug.) 1911.

It may come as a surprise to those who have been taught the interrelation between calcium and soaps in the stools that this was not found constant in these observations. The excretion of soap was directly related to the type of stool, that is, to the water content and to the reaction of the stool. The excretion of calcium was closely related to the calcium intake. As has been pointed out before, the calcium absorption was much lower when diarrhea was present. Furthermore, the calcium absorption by rachitic infants was much lower than that by healthy infants, and the administration of cod liver oil regularly increased the absorption of calcium, unless diarrhea was present. This is in accord with much accumulated clinical experience.

THE PREVENTION OF FOOD WASTE

One of the many lessons learned from the World War was the value of food conservation. For two years, during the war, the people of this country responded willingly to the efforts of the food administration, and there resulted a saving both of a vast amount of raw food materials and of large sums of money. This was accomplished not only through limitation in the use of various foodstuffs, but also through the elimination and prevention of waste. Today the cost of living has made necessary the institution of more careful methods of buying and using food, but apparently the importance of determining the food waste has been forgotten. When one considers that in a large civil institution the total garbage for one week amounted to 10,000 pounds, a large portion of which was edible food, it is readily seen that the prevention of a part of this food waste would mean the saving of an appreciable sum in dollars and cents.

Prevention of this loss is not impossible, as is shown by Irons,¹ who recently discussed the results of detection and prevention of food waste in some of our hospitals, where "waste of food does not usually result from deliberate intent to destroy, but occurs rather because of failure to recognize waste, and because the system of handling food takes too little account of the needs, feelings and impulses of the ultimate consumer—the patient." Prevention of waste of necessity depends on its recognition. By a system of inspection and classification, the amount, character and source of the garbage can readily be determined, and the necessary waste separated from the unnecessary; and steps may then be taken to reduce or prevent this edible waste. In order to accomplish this, cooperation of the entire personnel is necessary, under adequate supervision of the persons in charge, who must be well acquainted with the patients, knowing many of their likes and dislikes, their needs and their peculiarities. The serving of good food on an attractive tray,

soon after its preparation, and in amounts to suit the individual, will result in marked suppression of the edible waste. One method of accomplishing the latter is by stimulation of friendly competition among the various supervisors in the many wards.

How efficient such methods proved to be is shown by the fact that in one of our large base hospitals the average waste of edible food for each person daily was reduced in four months' time from 1.85 ounces to 0.15 ounce. In a civil hospital of about 400 beds, the total daily garbage was reduced in a short time from 743 to 357.8 pounds. This saving was accomplished mainly through improved methods of handling and serving food in the wards. Similar efforts in the serving of the occupants of private rooms resulted in but little reduction of the total garbage.

If results such as these can be obtained easily and in a short time, certainly there are many hospitals not managed so carefully that could reduce their expenses to a considerable extent by the institution of methods of waste prevention. Such a system of waste control should include, in addition to proper buying, preparation and distribution of food, methods of separation of waste at its source, so that responsibility for it may be determined, and friendly competition between the administration of ward units in the hospital be established. Waste control might profitably be extended to clubs, hotels and private homes, for, while the waste occurs under much different circumstances, it is often even more glaring than in hospitals, and with much less excuse.

Current Comment

CATS AND HUMAN DIPHTHERIA

It is a widely accepted belief that cats may suffer from diphtheria and convey the infection to human beings, but there appears to have been little or no exact experimentation on this question. Several observers, particularly in England, have reported finding true diphtheria bacilli in the throats of cats, but these observations for the most part were made several decades ago. The epidemiologic evidence connecting cats with human diphtheria is circumstantial and does not carry conviction, although some of the instances reported are suggestive of possible contagion. Savage has recently reexamined the whole subject.¹ He obtained uniform and definite results in experiments with young kittens. The implantation of vast numbers of diphtheria bacilli into the nasal cavities were ineffective in setting up any general or local lesions, and the same was true when massive doses were applied by throat swabbing. In point of fact, the bacilli not only failed to infect but survived for only a short period, usually disappearing within twenty-four hours. Savage's experiments not only do not support the view that diphtheria is a naturally occurring disease of cats,

1. Irons, E. E.: Detecting Hospital Food Waste, *Mod. Hosp.* 11: 143 (Feb.) 1920.

1. Savage: *J. Hyg.* 18: 448 (Feb.) 1920.

but suggest that the mucous membranes of the cat are peculiarly unfavorable to the growth and persistence of the diphtheria bacillus. Similarly, the alleged epidemiologic evidence as analyzed by Savage is regarded as quite valueless, and he concludes that the view that cats can suffer from a naturally acquired disease caused by the diphtheria bacillus is entirely without foundation. Consequently there is no ground for believing that cats can serve as carriers of diphtheritic infection.

INTERNATIONAL SCIENTIFIC TERMS

The editor of the *Nederlandsch Tijdschrift* has been appealing to the profession in his country to "purify" the language, and use Dutch terms instead of the foreign terms with which medical writings are now larded. He cites as examples "zenuwverzorging," and "zenuwknopcel," which he would theoretically prefer to have used instead of "innervatie" and "gangliencel," the terms now in vogue. He admits that the latter sound better to the present generation, trained in their use, and states that the efforts for "purification" of the language must have the future in mind, striving for better things in the rising generation. Trenchant comment on his reactionary views is a news item in the same issue relating that a German army physician at Namen in Belgium, during the German occupation, gave a prescription to the Belgian pharmacist to make up which called for "Hydrargyrum chloratum, 50 cg., 10 stück." The pharmacist supposed that mercuric chlorid was meant, and dispensed mercuric chlorid tablets in the legal form, that is, in a brown octagonal bottle labeled *Usage externe* and *Poison*. He wrote on the label besides, *Hydrargyrum chloratum*. . . . *Sublimé corrosif*. The physician assumed that calomel had been dispensed, as he had ordered, and poisoning resulted. Calomel in German is hydrargyrum chloratum, while corrosive mercuric chlorid is hydrargyrum bichloratum. The pharmacist was accused of trying to poison the Germans, and was saved only by the Belgian chief inspector of pharmacies, Dulière, explaining the mistake. In connection with the affair, the latter has appealed for uniformity in the nomenclature of official drugs in all lands, and urges the appointment of an international pharmacopeia commission for the purpose. One of the dangerous pitfalls for pharmacists and translators is the term "calcium chloratum," which does not mean "calcium chlorate" but "calcium chlorid" in English.

IMPORTANCE OF CHANGES IN THE PLASMA IN HEMOLYTIC ANEMIAS

The fact that the origin of many forms of anemia is still wrapped in obscurity is indicated by the nomenclature of the disease. We still speak of idiopathic anemias or primary anemias, or else we describe certain forms of anemia by the name of the person who first recognized the particular type. In recent years it has been recognized that there is one special group of anemias associated with destruction of the red blood corpuscles and usually described as the hemolytic anemias. There are, of course, some forms of hemolytic anemia, particularly those varieties due to definite

chemical poisons, the etiology of which is perfectly clear. On the other hand, there is a group of hemolytic anemias, of which the so-called "family jaundice" may be named as an example, wherein the method of action of the factors causing the hemolysis is still obscure. There are several possibilities in the method of production of abnormal blood destruction. It may be due to a normal mechanism acting on abnormally fragile corpuscles. It may be due to a hyperactivity of the normal blood-destroying function of the spleen. It may be due to substances in the plasma which either act as opsonins and render the red cells unusually susceptible to destruction or are themselves directly hemolytic. Gordon Ward¹ has attempted to group together a number of different blood syndromes which at first sight appear quite dissimilar, on the basis that all of them are due primarily to changes in the blood plasma rather than alterations in the blood-forming organs or in splenic blood destruction. The different conditions which Ward attempts to group together are the anemia of the family jaundice type; the anemia with sickle-shaped cells of Herrick; the condition described by Dresbach in which oval or elliptic cells occur in human beings; familial auto-agglutination, and the so-called Malin syndrome, in which anemia and splenomegaly are accompanied by the presence in the peripheral blood of large phagocytic cells. Ward's attempt to group these cases on the basis of similarity as regards their occurrence both as sporadic and as familial diseases, their intermittence in course, the fact that changes in the red cells peculiar to the disease occur and that all show plasma changes, is not entirely convincing. Nevertheless his article is an interesting and stimulating one, and calls attention to the necessity for more extended observations on the blood plasma in the anemias of this type.

AVOCADO FAT

Among the fruits that enter into the dietary of man the avocado, or alligator pear, takes an almost unique place because of its richness in fat. A few fruits may furnish a noticeable quota of real nutrients in the form of starch and, particularly, sugars; thus an ordinary sized banana is rated at a food value of 100 calories or more. But for the most part the fruits that enter into the ordinary regimen, however palatable, wholesome and dietetically valuable they may be, can scarcely be rated as significant sources of energy. The part that they play in nutrition must be estimated from other standpoints. Accordingly, an edible fruit that may exhibit as much as 20 per cent. of fat² in its make-up is worthy of special consideration. It may prove, for example, to become a valued adjuvant to the dietary of the diabetic, from which the carbohydrate content of many common fruits unfortunately excludes them. The possibilities of the avocado have been further promoted by recent investigations³ in California and Washington, both of which agree in assigning an excellent utilization to avocado fat, even

1. Ward, Gordon: Proc. Roy. Soc. Med. (Sect. Med.) 13:1 (Nov.) 1919.

2. Condit, I. J., and Jaffa, M. E.: Bull. 254, California College Agr. Expt. Station, p. 381, 1915.

3. Mattil: Ann. Rep. California Avocado Assn., 93, 1916. Holmes, A. D., and Deuel, H. J., Jr: J. Biol. Chem. 41:227 (Feb.) 1920.

when as much as 124 gm. (about 4½ ounces) a day were consumed. Heretofore the market price of this fruit has prohibited a very widespread use of what now appears to be a nutritious as well as palatable food. The avocado is indigenous to tropical and sub-tropical regions in the western hemisphere; but it is being cultivated to an increasing extent in Florida and California, and may ultimately become available at more reasonable prices in harmony with the history of some other tropical fruits. Dietotherapy will testify that the enrichment of the dietary with a really palatable source of fat will not be unwelcomed in the management of certain nutritive disorders. Ordinary cream rarely exceeds the avocado in available fat content.

Association News

THE NEW ORLEANS SESSION

Special Arrangements for Golfers

The American Medical Golfing Association announces that entries will be received up to and including April 15 for the tournament to be held in New Orleans on Monday, April 26. The tournament fee (\$1) must be deposited at the time the applicant submits his entry. His handicap must be approved by the handicap committee. Plans are being considered for engaging a summer hotel about a half mile from the golf course for the use of those who desire to be lodged near to the course. In order to obtain a reservation at this hotel, it is advisable to telegraph to Dr. John B. Elliott, Jr., 931 Canal Street, New Orleans, chairman of the golf committee, advising what space you would like to have. The consummation of the plan will depend on the demand for these accommodations. Address enrolment, entries and handicaps to the Secretary of the American Golfing Association, Dr. Will Walter, 1414 Chicago Avenue, Evanston, Ill.

Health Sunday

Governor Pleasant, without proclamation, has designated the setting aside of Sunday, April 25, as health Sunday for Louisiana. This is the Sunday preceding the Annual Session of the American Medical Association in New Orleans.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ILLINOIS

Physician Taken to Prison.—Dr. George W. Alverson, Macomb, who was sentenced to life imprisonment in connection with the death of Lawrence Clugston, is said to have been taken to the state penitentiary, Joliet, March 16.

Municipal Venereal Disease Clinic.—The city council of Peoria, March 2, unanimously provided an ordinance for the establishment of a municipal clinic for the treatment and isolation of venereal diseases. The ordinance provides for a commissioner of the dispensary with a salary of \$3,000 a year and with authority to declare quarantine if certain phases of the ordinance are not observed.

Hospital Notes.—The two-week drive for the Victory Hospital at Waukegan, which has been carried on under the leadership of Hon. C. C. Edwards, came to a close, March 22, with a total contribution of \$300,000. The institution, which will be for soldiers and sailors, will, it is said, be erected within two years.—The contract has been let for

the erection of a new modern hospital for the Cunningham-Deaconess Home, Urbana.

Speedway Hospital.—Contracts have been signed turning over the Speedway Hospital to the U. S. Public Health Service. Congress has appropriated \$3,500,000 for the acquisition of this plant and \$1,500,000 in addition will probably be required before the institution is completed. The hospital site includes 320 acres, and the buildings are fire-proof. The main building is 2,040 feet in length, 50 feet in width and four stories in height, and will accommodate between 2,000 and 2,500 patients. The institution will be completed within four months and will be known as the Broadview Hospital.

Chicago

Indicted for Failure to Report Disease.—Dr. Anna Sorna is said to have been indicted by the grand jury, March 18, for failure to report a case of scarlet fever.

Grenfell in Chicago.—Dr. Wilfred T. Grenfell, the medical missionary to Labrador, with Mrs. Grenfell, was a visitor in Chicago last week, and spoke at St. Chrysostom's Church and at the community house in Winnetka, March 21.

Midwives Fined.—Mrs. Wanda Grzybowski was fined \$25 and costs, March 16, for failing to apply silver nitrate to the eyes of a new-born babe, and for failing to report the birth.—Mrs. Kate Kijowska was fined \$15 and costs for a similar offense.

Midwife Freed of Charge.—Mrs. Catherine Schmidt, a midwife, was released from police custody, March 6, after having been held for two weeks in connection with the death of Mrs. Grace D. Frey, who died, February 24, supposedly as the result of a criminal operation.

Health Commissioner to Open Hospital.—Health Commissioner John D. Robertson announces that he will open a new charity hospital, April 1, with accommodation for twenty patients. This hospital will also afford means by which nurses may obtain a training course in three months. This will be conducted in the City School for Home and Public Health Nursing at Fulton and Ada streets. A charge of \$50 will be made for the course.

Robert Koch Society Meeting.—The thirtieth annual meeting of the Robert Koch Society for the Study of Tuberculosis was held, March 25, at the City Club. Dr. Benjamin H. Orndoff spoke on "The Peritoneoscope in Diagnosis of the Diseases of the Abdomen"; Dr. Max Biesenthal discussed the "Use of Sodium Gynocardate 'A' in Pulmonary Tuberculosis," and Dr. James A. Britton spoke on "Occupation and Tuberculosis."

Relief for Suffering Vienna Physicians.—At a luncheon given by the Chicago Medical Society and affiliated organizations, March 15, the sufferings of the wives and families of Vienna physicians were detailed by Dr. Carl Beck, and a committee was appointed to solicit funds. The personnel of this committee is Dr. Rudolph W. Holmes, chairman of the committee of the specialist societies; Dr. Coleman G. Buford, chairman of the branch societies of the Chicago Medical Society; Dr. Effie L. Lobdell, chairman of the Chicago woman's medical societies and clubs, and Dr. Warren Johnson, chairman of the club and social associations. A contribution of \$1,000 by Mrs. Catherine McCormick was announced by the association.

INDIANA

Fire Destroys Sanatorium.—The Mudlavia Springs Hotel and Sanitarium has been completely destroyed by fire. It was established in 1889 and had a capacity for 200 patients.

Venereal Disease Clinic Reopened.—The Fort Wayne Venereal Clinic reopened, February 23, in its quarters on the second floor of the Wayne pharmacy building with Dr. George Rea and a registered nurse in charge.

Public Health Association Election.—At the annual meeting of the Logansport Public Health and Welfare Association, March 9, Dr. John A. Little was reelected president; Mrs. W. J. Ballard and Mrs. Willard Wynne were made vice presidents; Mrs. William A. Gremelspacher was elected secretary, and C. W. Graves, treasurer.

War Histories of Medical Officers Wanted.—The Indiana Historical Commission is now engaged in collecting and compiling the official war history of the state and has entrusted to Post 26, Indiana Branch, the American Legion, the duty of preparing a complete military history of the physicians of Indiana who were in the service. All Indiana physicians who were in service are requested to write imme-

diately to Dr. John R. Newcomb, Commander, Post 26, American Legion, Indianapolis, for proper blanks on which to file their military records.

IOWA

Tuberculosis Clinic Established.—A tuberculosis dispensary clinic has been opened at the community hospital, Grinnell, under the care of Dr. Edwin E. Harris, secretary of the hospital staff. The clinic will be at the disposal of the American Red Cross for use during the tuberculosis survey. —A free child welfare clinic has also been established at the hospital.

Personal.—Dr. Enos D. Miller, Wellman, suffered a fracture of two ribs and other injuries when his automobile backed down a hill and went into a creek, March 11.—Dr. Oscar A. Dahms has been reelected president of the Davenport school board.—Dr. Charles F. Applegate, superintendent of the Mount Pleasant State Hospital, has been appointed medical superintendent of the Norwalk State Hospital, Norwalk, Calif., and assumes his new duties April 1.

KENTUCKY

Hospital Purchases Y. M. C. A.—Madisonville Hospital Association has purchased the Y. M. C. A. building with the idea of making improvements and using it as a hospital.

Suit Settled.—Under terms of a settlement said to be \$1,000, the damage suit for \$30,000 brought by Mrs. Francis Jernigan against Dr. Alex. C. Foster, Owensboro, has been dismissed.

Personal.—Dr. Thomas D. Moore, Hopkinsville, has been appointed to a fellowship in general medicine with the Mayo Foundation, Rochester, Minn.—Dr. John H. Hamilton, Owensboro, has been appointed full-time health officer of Davies County.

Venereal Quarantine.—A joint federal, city and county quarantine and sanatorium for the women now quarantined in the county jail, has been arranged for at the Louisville City Work House. Reduction in the number of prisoners from 250 before July 1 to fifty at the present time makes this possible. Sixteen to thirty women are constantly under segregation and treatment. Every effort to effect the moral and social regeneration of the women will be made.

Alumni Association Progress.—As a result of a concerted effort to reorganize the Alumni Association of the University of Louisville Medical Department, more than 1,000 graduates have been enrolled. Elaborate plans are being made for a meeting during commencement week, May 31 to June 5, when clinics and entertainments will be held. The clinics will consist of operative clinics at all of the hospitals; bedside clinics and ward walks; demonstrations in laboratory methods of diagnosis, lectures, etc. Over four hundred are expected to attend. The 1920 graduating class will be guests of honor at a banquet.

LOUISIANA

Office Building for Physicians.—A three-story office building to be used exclusively by physicians and dentists will be built at the corner of Prytania and Delachaise streets, New Orleans, across the street from the Touro Infirmary. The building will represent an investment of \$150,000.

Parish Physicians Meet.—At the annual meeting of the Lafourche Parish Medical Society held in Thibodaux, March 15, Dr. Joseph M. Hubert, Allemands, was elected president, Dr. Ewell A. Kleinpeter, Thibodaux, vice president, and Dr. Philip J. Dansereau, Thibodaux, secretary-treasurer.

Personal.—Dr. Alexander R. Crebbin, New Orleans, has sailed from London for New York.—Dr. Elizabeth D. A. Cohen, New Orleans, who has been for thirty years at the Touro Infirmary celebrated her hundredth birthday, February 22.—Dr. Guy A. Darcantel has been appointed a member of the municipal health board of White Castle.

License Refused.—The refusal of the state board of medical examiners to reissue a license to practice to Dr. Antonio B. Jannarelli, New Orleans, is said to have been upheld in the civil district court, March 8, when the physician's suit to compel the board to license him was dismissed by Judge Parker.

Appropriation for Health Work.—The appropriation committee of the Senate has allowed \$200,000 for the rat-proofing work which the U. S. Public Health Service is conducting in New Orleans.—The state council of defense has approved the recommendation of the executive council for the appro-

priation of \$10,000 for the state board of health for use in the campaign against venereal disease and of \$6,000 to combat bubonic plague.

MAINE

Personal.—Dr. Ludovic J. Dumont has been appointed health officer of Lewiston for three years, and the local board of health has been abolished.

Laboratory Soon to Be Opened.—The Aroostook branch laboratory of the state department of health at Presque Isle will soon be opened and will be in charge of a trained chemist and bacteriologist. In this laboratory, tests for typhoid fever, diphtheria, and tuberculosis and also examinations of water will be made.

MARYLAND

Libraries to be Consolidated.—According to plans now under consideration by the authorities at Johns Hopkins University, the libraries of the hospital, the school of hygiene and the medical school will be collected under one roof, in a new library building to be erected in the hospital group.

Osler Memorial Meeting.—A memorial meeting to the late Sir William Osler, regius professor of medicine at Oxford University, and for many years professor of medicine at the Johns Hopkins University, was held March 22, in the civil engineering building, Johns Hopkins University. President Frank J. Goodnow presided, and addresses were made by Henry Van Dyke, D.D., and Prof. William H. Welch.

Personal.—Dr. John M. T. Finney, Baltimore, has been elected an honorary fellow of the Royal College of Surgeons, England.—Dr. James A. Nydegger, Baltimore, in charge of the U. S. Public Health Service in Baltimore, has announced the addition of two physicians to the staff. Dr. George Walker has been appointed consultant neurologist and Dr. George Lane Taneyhill, Jr., neuropsychiatrist.—Dr. Ross McC. Chapman, chief executive officer of St. Elizabeth's Hospital, Washington, D. C., who has been appointed medical superintendent of the Sheppard and Enoch Pratt Hospital, will assume his new duties April 1.

Movement Launched for New Municipal Hospital.—A movement to have Baltimore take over the hospital at Fort McHenry for a general municipal hospital as soon as the War Department gives it up has been launched. Through a petition handed the mayor, the Baltimore City Medical Society has asked that hospital facilities for Baltimore city be provided as quickly as possible and endorsed the acquisition by the city of the hospital at Fort McHenry, if this could be effected. Dr. John M. T. Finney, Baltimore, has been named by the mayor as chairman of a committee to lay the plan before the Secretary of War and the Surgeon-General of the Army. It is said that this transfer could be made by July 1, provided the plan is put through at once. The only obstacle seen is a possibility that the U. S. Public Health Service may need the hospital for its war risk insurance work. This phase of the situation will be looked into by Dr. Finney and his committee. In the event that the Fort McHenry Hospital is acquired by the city, Sydenham Hospital, the city hospital for infectious diseases, will probably be put to other use.

MASSACHUSETTS

Animal Tuberculosis.—At the request of the mayor, of the director of public health and charities and other officials of Lawrence, Dr. E. A. Crossman of the Bureau of Animal Industry, Department of Agriculture, delivered an address, February 25, before the citizens of Lawrence and vicinity on "The Tuberculous Cow, a Menace to Public Health."

Personal.—Dr. George Forrest Martin, Lowell, has been nominated as a trustee of the state infirmary, succeeding Leonard Huntress, deceased.—Dr. William Hall Coon, Haverhill, has accepted a position of health commissioner in Bridgeport, Conn.—Dr. Otis P. Mudge has been elected a member of the board of health of Amesbury.

MICHIGAN

Hospital Burns.—The Red Cross Emergency Hospital at Mount Pleasant was recently destroyed by fire.

Medical Building Association Organized.—Twenty-five physicians and dentists of Flint have incorporated the Flint Medical Building Association for the purpose of erecting a six-story building to be devoted exclusively to the use of members of these professions.

Personal.—Dr. Mary J. Erickson, Newberry, has been placed in charge of the research work of the Iowa state board of health under the recent appropriation of the federal government for investigation in the field of venereal disease and has commenced her work at the University of Iowa, Iowa City.—Dr. Herbert L. Wright, city health director of Lansing, has resigned, his resignation to take effect March 15. He has been appointed director of a department of the state board of health of Texas, with headquarters at Austin.

MINNESOTA

Personal.—Dr. Charles H. Mayo, Rochester, has been elected an honorary fellow of the Royal College of Surgeons, England.—Prof. Frank C. Whitmore of the University of Minnesota has succeeded Prof. Harry A. Curtis as professor of organic chemistry in Northwestern University, Evanston, Ill.

MISSOURI

Dinner to Dr. Bowen.—The roentgenologists of St. Louis gave a dinner, March 23, in honor of Dr. Charles F. Bowen, Columbus, Ohio.

Health Center for Women.—Dr. Eva M. Blake, New York City, arrived in St. Joseph, March 8, and spent a week in cooperation with the Y. W. C. A. in establishing a health center for women. Public meetings of women of all ages were held during the week and intensive health work was done.

Salary Increase.—Taking advantage of an act of the last legislature conferring authority on the governor and state auditor, these officials have increased the salaries of the superintendents of state insane hospitals \$50 a month, and have extended the same increase to the superintendents of the State Sanitarium for the Treatment of Incipient Tuberculosis, Mount Vernon, and the superintendent of the Missouri Colony for Feeble-minded and Epileptics, at Marshall. The physicians at these institutions will also have an increase in salary of \$300 a year.

Personal.—Dr. Eugene Lee Myers, formerly professor of otorhinolaryngology at the St. Louis College of Physicians and Surgeons, is no longer connected with that school.—Dr. Ulysses F. Kerr, Springfield, has been appointed deputy commissioner of health of Greene County.—Dr. Edward E. Mansur, Jefferson City, was operated on, February 21, at St. Mary's Hospital for appendicitis and has made a good recovery.—Dr. Frederick E. Woodruff, St. Louis, has been appointed chairman, and Dr. John Green, Jr., St. Louis, secretary of the consulting staff of oculists of the Missouri Council for the Blind.—Dr. Walter J. Hansen, St. Joseph, formerly county physician of Buchanan County has been appointed deputy state health commissioner.—Dr. G. Canby Robinson, dean of Washington University Medical School, St. Louis, has resigned to accept the position of dean and professor of medicine in Vanderbilt University, Nashville, Tenn.

NEW YORK

State May Buy Radium.—A bill known as the Gibbs bill is before the legislature which authorizes an appropriation of \$250,000 for the purchase of 100 grains of radium. It is understood that the state finance committee will recommend this purchase. The radium will be for use in the State Institute for the Study of Malignant Disease, Buffalo.

Health Insurance Bill in Legislature.—Senator Frederick M. Davenport, Oneida, recently introduced a health insurance and public welfare bill into the legislature. In introducing the bill Senator Davenport said he would not urge its adoption at this session until "the hidden and selfish purpose behind the organized and powerful propagandism and lobbying of certain purely business groups opposed to health insurance could be disclosed." He believes that at present an honest opinion on the merits of the principle cannot be obtained inside the realm of industry. The bill now introduced is somewhat less wide in its scope than that of last year and applies to those employed persons who are defined as industrial workers under the existing workmen's compensation act. Senator Davenport asserts that this bill is not state insurance at all and that there is no state fund.

New York City

Encephalitis Epidemic.—Since January 1, about 175 cases of encephalitis lethargica have been reported in New York. This apparently followed the influenza epidemic and has caused forty deaths since the beginning of the year.

Harvey Society Lecture.—The eighth of the series of Harvey Society Lectures given by Dr. William McKim Marriott, professor of pediatrics in Washington University, St. Louis, at the New York Academy of Medicine, March 27, is on "Some Phases of the Pathology of Nutrition in Infancy."

Department of Public Charities Changes Name.—Mayor Hylan has approved the bill recently passed by the legislature amending the city charter so that the department of public charities hereafter will be known as the department of public welfare. The reason for this is that the name "public charities" had come to be a burden to the department. Commissioner Coler of this department announces that, owing to the influence of prosperity, prohibition and wood alcohol, the maintenance of the municipal lodging house is no longer necessary.

Nightingale Centennial.—Among the features of the celebration to commemorate the hundredth anniversary of the birth of Florence Nightingale will be the inauguration of a campaign to recruit 30,000 young women in training schools for nurses and the award of a prize of \$500 for the best three act play by an American author based on incidents in the life of Florence Nightingale. Pageants, public meetings, and formal ceremonies will be held on the anniversary date, May 12, in which nursing organizations, women's clubs and colleges will cooperate.

NORTH CAROLINA

Personal.—Dr. John M. Manning, Durham, has been appointed state medical examiner for the Modern Woodmen of America.

State Society Meeting.—The annual meeting of the Medical Society of the State of North Carolina will be held in Charlotte, April 20 to 22, under the presidency of Dr. John P. Munroe, Charlotte.—The North Carolina Hospital Association will hold its annual meeting in Charlotte, April 19.

County Hospitals Advocated.—The bulletin of the University of North Carolina in a recent issue carries a report to the university club strongly advocating a system of county hospitals owned and operated at public expense as a state-wide system, logically urging that only by public support through systematic taxation can the hospitals be freed from the everlasting grind and strain for funds adequate for maintenance, and also that only by such a system can all the people and property be caused to carry their proper burden of the care of the sick.

OHIO

Hospital Donated to Town.—Charles F. Kettering, a millionaire inventor and manufacturer of Dayton, has donated a hospital to Loudenville.

Hospital Plans Approved.—The city council of Youngstown, March 1, approved the original plans of the Youngstown Municipal Hospital to cost \$620,000.

Scarlet Fever in Cleveland.—Dr. Harry L. Rockwood, city health commissioner of Cleveland, announces that there are about 400 cases of scarlet fever scattered about the city, and that the disease is epidemic in the state and especially in Cincinnati, Columbus and Toledo.

Fires in Epileptic Hospital.—A fire, March 9, destroyed one cottage and the dancing pavilion of the Ohio Hospital for Epileptics, Gallipolis. Eight patients are dead and two, who were injured, are expected to die. Twenty-five patients were in the cottage at the time. March 10, the hospital, was again set on fire. No clew to the incendiary has been found.

Health Commissioners Organize.—A permanent organization of the county health commissioners of the northern district of Ohio was made at a meeting held in Canton, March 10, at which ten of the thirteen counties of the district were represented. Dr. K. N. Schwartz, Lisbon, was made president of the new organization and Dr. Chester M. Peters, Canton, secretary. The association will meet once a month.

Academy Activities.—March 5, Dr. George Walker, Baltimore, formerly colonel, Urological Division, M. C., U. S. Army, delivered an address before the Academy of Medicine in Cleveland on "Abolition of Venereal Disease by Medicinal Prophylaxis."—February 20, Dr. Carl A. Hedblom, Rochester, of the surgical division of the Mayo Clinic, Rochester, delivered an address on "Treatment of Chronic Empyema."—At the March 19 meeting of the academy, Dr. Harry G. Sloan, Cleveland, spoke on "Gas Cysts of the Intestine," and Dr. John Phillips, Cleveland, on "The Effort Syndrome."

Personal.—Dr. Roy L. Pierce, Mount Gilead, has resigned as health commissioner of Morrow County, as no funds were available to carry on the work.—Dr. John H. Elias, Murray City, has been elected health commissioner of Hocking County.—The home of Dr. Paul J. Hanzlik, Cleveland, assistant professor of pharmacology in Western Reserve University was entirely destroyed by fire, February 11. Dr. Hanzlik and his wife sustained burns and other injuries from which they are recovering.—Dr. Presley C. Ramsey, Alliance, has been appointed city health commissioner.—Dr. Charles R. Keyser, Van Wert, has been elected health commissioner of Van Wert County.—Dr. William L. Dick, Columbus, will continue as acting city health officer and medical inspector of Columbus.—Dr. John T. McVey of the staff of the Ohio Hospital for Epileptics, Gallipolis, has been made a member of the staff of the Massillon State Hospital.—Dr. Roy K. Evans, McGuffey, has been selected health commissioner of Hardin County.—Dr. H. H. Pansing, Miamisburg, has been appointed health commissioner of Montgomery County.

OKLAHOMA

Shortage of Physicians.—Dr. Arthur A. Lewis, Oklahoma, state health commissioner, reports a serious shortage of physicians in the small towns in Oklahoma.

Personal.—Dr. James S. McFadin, Hollis, was struck and injured by a cab, March 3.—Dr. Virgil Berry, a pioneer practitioner of Okmulgee, announces his retirement from active practice.—Dr. William A. T. Robertson has been elected president of the Ponca City Medical Association.

Hospital Unveils Tablet.—The Sisters of St. Francis of St. Anthony's Hospital at Oklahoma City have recently unveiled a bronze tablet in memory of Major Robert Lord Hull and Capt. Frank Bruner Sorgatz, both of whom lost their lives in the military service during the influenza epidemic last winter.

PENNSYLVANIA

Personal.—Dr. Iden M. Portser, Greensburg, has resigned as a member of the state board of health.

State Health Organization Planned.—William J. Crookston, Pittsburgh, associate chief medical inspector of the department of health, outlined a plan at a recent conference of the field force of the department, whereby the state will be organized by counties for health education and preventive work and emergency service.

Physicians Indicted.—Dr. J. Newhall Kirk, Philadelphia, directing head of the "Associated Doctors," and two other physicians, Dr. Guy V. Payne and Dr. Grant F. Hartzell, are reported to have been indicted, January 27, charged with conspiracy to defraud. Dr. Payne is reported to have been indicted also for practicing medicine in Maryland without a license. The report states that Dr. Kirk is accused also by the Philadelphia authorities of violating the Pennsylvania law prohibiting the advertisement of cures and treatment for specific diseases and that on this charge he was held in \$5,000 bail.

Philadelphia

Personal.—Dr. Lawrence F. Flick was awarded the Laetare medal for 1920 by the University of Notre Dame, Ind., March 13. The honor is regarded as one of the highest that can be conferred on any Catholic layman in America and is for "distinctive service in behalf of God, church and country."—Dr. Thomas A. Shallow, chief physician of the medical department of the municipal court, will hereafter sit with the judge to give the benefit of an expert medical opinion at the regular Wednesday juvenile court hearings.

Medical Co-Eds Opposed.—On the ground that valuable parts of the courses have to be omitted lest they offend the sensibilities of the women, students and professors at the Medical School of the University of Pennsylvania are demanding the exclusion of co-eds from medical class rooms. A petition presented to Provost Smith and Dean Pepper has been referred to the board of trustees for action. The students and some of their instructors say women who desire to study medicine should go to a women's medical college.

UTAH

Personal.—Dr. James M. Elliott has been named as sanitary inspector and member of the board of health of Ogden, succeeding Mr. George Shorten.—Dr. Willard Christopher-

son has succeeded Dr. Samuel G. Paul as head of the city board of health of Salt Lake City.

VIRGINIA

Personal.—Dr. William F. Reasner, Portsmouth, who has served as health director of Norfolk County, has gone to Minneapolis to become assistant director of the health department of that city.—Dr. C. Curtis Hudson, Richmond, has been appointed chief health officer for Richmond.

Surgeon at Penitentiary.—The house committee on prisons and asylums has reported favorably a bill providing for a surgeon-general at the state penitentiary with a salary of \$3,000 a year, whose time is to be devoted entirely to prison work. He will exercise supervision over all surgical and medical work at the state prison, state farm and convict road camps.

Health Campaign Opened.—Halifax County last month launched a twelve-month sanitation unit under the charge of Dr. Walter A. Newman as field director. One half the expense of this work will be borne by the county and the remainder jointly by the state department of health and the international health board.—The result of the year of intensive health work just closed in Fairfax County has been so successful that the county has determined to continue the work at its own expense and has appointed Dr. Edward L. Flanagan, Fairfax, to continue as field director.—Albemarle County is preparing for a similar health crusade.

CANADA

Personal.—Dr. Arthur Doull, Halifax, D.P.H., has been appointed provincial inspector of health for Nova Scotia.—Dr. Allan C. Rankin, Edmonton, director of laboratories of the provincial department of health, Alberta, has been made dean of the medical faculty of the University of Alberta, Edmonton, Alta.—Dr. John J. Ower, Montreal, has been appointed professor of pathology in the medical faculty of the University of Alberta.—Dr. Arthur C. Jost, Guysborough, has been appointed provincial medical officer of health for the eastern health division of Nova Scotia.—Dr. John P. Brown, Toronto, D.P.H., has received an appointment in the dominion government quarantine service and has been assigned to duty at the quarantine station, St. John, N. B.

GENERAL

Anesthetists to Meet in New Orleans.—The American Association of Anesthetists will hold its eighth annual meeting at the Hotel Grunewald, New Orleans, April 26 and 27, under the presidency of Dr. Albert H. Miller, Providence, R. I. The annual dinner will be held on the evening of April 26.

Proctologists to Meet.—The twenty-first annual meeting of the American Proctologic Society will be held in Memphis, Tenn., April 22 and 23, under the presidency of Dr. Collier F. Martin, Philadelphia. The society will be the guest of Dr. John L. Jelks, and of the Memphis and Shelby Medical Society with headquarters at the Hotel Gayoso.

Medical Intern Wanted.—The United States Civil Service Commission announces that an open competitive examination will be held for the position of medical intern in St. Elizabeth's Hospital, Washington, D. C., with a salary of \$1,200 a year and maintenance. Appointees whose services are satisfactory may be allowed a temporary increase of \$20 a month, granted by Congress.

Biography of Sir William Osler.—Dr. Harvey Cushing, Peter Bent Brigham Hospital, Boston, has been requested by Lady Osler to prepare a biography of Sir William Osler. He will be grateful to any one who will send him either letters or copies of letters, or personal reminiscences, or information concerning others who might supply such information. It is requested that a copy of all letters, no matter how brief, be sent, and that the dates be supplied whenever possible. If originals are forwarded they will be promptly returned by Dr. Cushing.

Coal Mine Fatalities.—Complete report of fatal accidents in coal mines during 1919 indicates a reduction of 273 fatalities, or 10.58 per cent., as compared with 1918, according to a statement issued by the United States Bureau of Mines. The decrease was noted mainly in accidents from mine cars and locomotives and in surface accidents, while increases are recorded in accidents due to gas and dust explosions and also explosives. While the actual number of deaths is con-

siderably less than in 1918, the ratio on the basis of tons of coal mined and number of working days is slightly higher.

Anesthesia Research.—At the meeting of the board of governors of the National Anesthesia Research Society held in Cleveland this month, it was voted that the annual convention of the society be held at Pittsburgh during the week of October 4, in conjunction with the meeting of the Interstate Anesthesia Association and the Medical Society of the State of Pennsylvania. The governors voted \$200 to be apportioned in prizes for the best papers on research in anesthesia, and a committee was also appointed to prepare forms for uniform anesthesia charts.

Fraternity Favors Public Health and Sanitation Department.—At the recent convention of the Alpha Kappa Kappa Medical Fraternity, at Chicago, the following resolution was passed:

WHEREAS: The various industries, professions and labor of these United States have received official recognition, by the establishment of representatives in the President's cabinet; and

WHEREAS: The medical profession is not in any way recognized as a whole, but considered a part of the various departments; be it therefore:

Resolved, That the twentieth convention of Alpha Kappa Kappa Medical Fraternity does go on record as being in favor of the creation of a department of public health and sanitation, with a representative on the President's cabinet. Be it further:

Resolved, That a copy of this resolution be sent to the President of the United States, and the President of the American Medical Association.

Bequests and Donations.—The following bequests and donations have recently been announced:

Presbyterian Hospital, Chicago, and Evanston, Ill., Hospital, each \$25,000 by the will of Frank H. Armstrong.

Presbyterian Hospital and New York Hospital, New York City, each at least one million dollars by the will of Charles D. Thompson.

Middlesex Hospital Medical School, London, \$100,000 for the endowment of a chair of physics by Messrs. J. B. and S. B. Joel.

Presbyterian Hospital, Philadelphia, \$40,000 for the endowment of a bed available after the death of his mother and two sisters, by the will of Robert Wilson.

Howard University, Washington, D. C., a gift of \$250,000 for endowment fund by the Rockefeller Foundation.

Milwaukee Associated Charities, Milwaukee Children's Hospital, and Marquette University, Free Medical Dispensary, Milwaukee, each one third of the annual cash income of \$10,868 from the estate of Helene M. Cudahy.

Vanderbilt Clinic of the College of Physicians and Surgeons and Presbyterian Hospital, Tuberculosis Clinic, New York City, each \$9,000; New York Association for Improving the Condition of the Poor, Home Hospital, New York City, \$8,000; Loomis, N. Y., Sanatorium, and Trudeau, N. Y., Sanatorium, each \$3,000; Stonywald Sanatorium, Lake Kashaqua, N. Y., \$2,000; Hospital and House of Rest for Consumptives, Inwood, N. Y., \$1,000, and Henry Street Settlement for Tuberculosis Nursing, New York City, \$500, donations made at the annual meeting of the trustees of the East River Homes Foundation.

FOREIGN

Personal.—Prof. Hugo Fuchs, professor of anatomy at the University of Königsberg, has been transferred to the University of Göttingen, succeeding Professor Merkel.

Honorary Degree Conferred on Hoover.—The University of Cracow, Poland, has conferred the honorary degree of Doctor of Medicine on Mr. Herbert Hoover for services rendered to Poland.

Osler Institute to Be Established.—At a public meeting held March 7, at Oxford University, it was decided to establish the Osler Institute of General Pathology and Preventive Medicine as a permanent memorial to the late Sir William Osler.

Appropriation for East African Hospital.—The United States consul at Lourenco Marques, Portuguese East Africa, reports that the local government has authorized a special loan of \$194,660 for electrotherapy, hydrotherapy and radiotherapy at the Hospital Miguel Bombarda of that city.

Second Centennial of Death of Lancisi.—A meeting in honor of the memory of the Italian physician and anatomist, G. M. Lancisi, who died in 1720, was held recently at Rome in the Lancisi library. Senator Marchiafava delivered the main address. Professor Lancisi is known by the nerve of Lancisi and his numerous published works, including the history of five great epidemics in Italy.

Seeks Relief for Germans.—Dr. O. Edward Janney, Baltimore, representing the American Friends Service Committee for the relief of suffering children in Germany is organizing citizens' relief committees to raise money for this work. One million dollars worth of supplies have already been sent to Germany by the committee and in the next three months

\$12,000,000 will be needed. The committee has already thirty relief workers in Germany.

Red Cross in Charge in Esthonia.—The American Red Cross Commission at Reval, Esthonia, has been invested with authority to take any measures, political or economic, to stamp out the epidemic of typhus fever raging there, to put the country under strict quarantine, to interdict travel and to enforce any other measures which may be deemed necessary by Lieut.-Col. Edward J. Ryan, chief of the commission.

Practice in Norway.—The *Deutsche medizinische Wochenschrift* states that the medical faculty of the University of Christiania has recommended that foreign physicians be allowed to practice in Norway provided that they locate at points where there is a pressing demand for physicians. The journal adds, "This seems to indicate that there is a scarcity of medical men in the rural districts of Norway."

Death of Morelli.—Prof. Enrico Morelli of Rome, who with Baccelli and Durante founded the *Policlinico* twenty-seven years ago, died February 13. He gave up most of his practice and his teaching to devote his energies to this leading medical journal which has always taken a high stand in science and in promoting the best interests of the profession. He was editor and manager both of the weekly practical section and of the monthly medical and surgical sections.

LATIN AMERICA

Influenza in Mexico.—The authorities announce that the influenza epidemic has come to an end. The number of deaths this year was 1,649, while last year there were more than 3,000.

Department of Health in Santo Domingo.—According to a measure approved by the military authorities, a department of public health and charities has been created in Santo Domingo to have complete charge of these matters.

Encephalitis Lethargica in Mexico.—There has been a case of encephalitis lethargica in Mexico City. The patient was taken as insane to the asylum, where the diagnosis was made. Other cases have occurred at Monterey and Laredo.

Sanitation Works in Peru.—A bill now pending in the Peruvian senate empowers the president to enter into contracts for the execution of the work necessary to provide Lima and thirty other cities with safe water, drainage, garbage disposal works, etc. The improvements contemplated involve an expenditure of several millions of dollars.

Quarantine Station in Colombia.—A recent law appropriates 30,000 pesos for the construction of a quarantine station and a hospital in the port of Riohacha. Eight thousand pesos are also provided to build a water works system, and an annual appropriation of 5,000 pesos for each milk station that may be established in the capitals of any of the different departments.

New Medical Journal in Central America.—Under the editorship of Dr. Rodolfo Espino, there has been founded in Managua, Nicaragua, a new medical journal, entitled *Revista de la Asociación Médica Centroamericana*. Its avowed purpose is to promote the union of the medical profession of the five Central American countries, and a medical congress, which will be held, Sept. 15, 1921, on the anniversary of the independence of the five republics.

Deaths in the Profession.—Dr. Manuel Pérez, director general of the public health service of Paraguay, delegate to various international medical congresses, and professor in the medical school at Asunción while it existed, aged 39.—Dr. F. C. de Sá Ferreira, the dean of the psychiatrists in charge of the insane of the Rio de Janeiro district, aged 77.—Dr. Antonieta Dias Morpurgo, a leading woman physician and pediatricist of Rio de Janeiro, aged 49.—Dr. G. A. de Carvalho, also of Rio, aged 70.

Personal.—Dr. Bernardo Etchepary, a prominent physician of Uruguay, who came to this country to conduct scientific studies on behalf of the Board of Health of Uruguay, has returned to his country, accompanied by his wife and son. While here, Dr. Etchepary visited the most important eastern cities.—Prof. P. Pereira, professor of histology at the University of Bahia and director of the *Gazeta Médica da Bahia*, was recently elected honorary member of the Academia Nacional de Medicina, on the fifty-third anniversary of his entering on his professional career.—Dr. J. Moreira da Fonseca of Rio de Janeiro was elected by the same Academia to the post left vacant by the death of Dr. Miguel Pereira. His address was on suprarenal insufficiency in influenza.

Government Services

Aeroplane Ambulances

Orders have been received to redesign and construct four DH-4 aeroplanes into models for ambulance purposes. Each machine will have accommodation for pilot, and two patients set in ship horizontally on Stokes Navy litters.

Health Conditions in the Army

The health of the troops continues excellent. A few cases of influenza appear, but in decreasing numbers. Measles is increasing in a few stations, twenty-two cases being reported from Camp Upton and fifteen new cases from Camp Knox. The admission and non-effective rates are as low as expected under normal conditions. Health conditions among troops in Germany and Siberia remain about the same.

Construction Work in Hospitals

In House Bill 8819, signed by the President, February 28, which provides for the purchase of property and certain construction for military purposes there appears a clause that "no provision contained in army appropriation act for June 11, 1919, be deemed or construed to prohibit the expenditure of the appropriation of \$350,000 made therein for the purchase of land contiguous to the Walter Reed General Hospital, 26.9 acres more or less, and the acquisition of so much of said acreage for the amount appropriated as the Secretary of War in his discretion may deem to be in the public interest."

Citation for Service

Col. Charles F. Morse, M. C., U. S. Army, has been awarded the Distinguished Service Cross for exceptional meritorious and distinguished services "as director of the veterinary corps, by displaying exceptional energy, zeal and good judgment he organized and administered with marked success a veterinary service capable of meeting every need in home territory and in the theater of operations. He provided effective means for the treatment of sick and wounded animals and for the prevention of disease among well animals, for the inspection of meat and dairy products used by the army, and, through establishment of schools of instruction, placed the personnel of the veterinary corps of the Army on a high plane of efficiency."

Citations by King for Medical Corps

The king of England has ordered certificates issued in the following form to Col. Christopher C. Collins; George W. Crile, Cleveland; Harvey Cushing, Boston; Mathew A. DeLaney; Robert U. Patterson; Harry L. Gilchrist; James D. Fife; Richard H. Harte, Philadelphia, and Lieut.-Col. Lucius L. Hopwood, M. C., U. S. Army, and to Miss Julia Stimson, superintendent of the nurses of the Medical Department, U. S. Army:

The war of 1914-1918. U. S. Army Medical Corps (name of recipient) was mentioned in a despatch from Field Marshal Sir Douglas Haig, K.T.G.C.B., G.C.V.C., K.C.T.E., dated Nov. 7, 1917, for gallant and distinguished services in the field. I have it in command from the king to record his majesty's high appreciation of the services rendered.

WINSTON S. CHURCHILL, Secretary of State for War.
War Office, Whitehall, R. W., March 1, 1919.

Medical Officers Under New Army Bill

According to the *Army and Navy Register* the Army reorganization bill, as it passed the House, contained a provision in the matter of promotion from a single list which, unless amended, would practically destroy the medical department. "In bringing medical officers into the single list for the purpose of equalizing promotion, which is the purpose of this new method of advancement, officers of the medical corps are placed on the list immediately below other officers of two years' longer service. This concession in the way of constructive service is altogether inadequate," says the *Register*, "and can only have a detrimental effect upon medical corps personnel. The provision in the Senate bill on Army reorganization, on which measure no action has been taken beyond reporting it from the military committee, is

much more satisfactory and it is probable that when the two rival measures get into conference the Senate provision will be agreed upon, inasmuch as Messrs. Kahn and Anthony of the House military committee, who will be members of the conference, have given assurance that the defects in this respect in the House bill will be corrected."

Increased Appropriation Asked for Public Health Service

The Secretary of the Treasury, D. F. Houston, in a formal letter to Congress has asked that the appropriation for the Public Health Service for the fiscal year 1921 be increased from \$8,000,000 to \$10,000,000. The reasons set forth for this increased expenditure are stated in the following letter of the acting Surgeon-General addressed to the Secretary of the Treasury.

Sir:—I have the honor to request that a letter be sent to the Speaker of the House of Representatives, asking that the estimate for appropriation for medical, surgical, and hospital services and supplies for war-risk insurance patients and other beneficiaries of the Public Health Service, etc., for the fiscal year 1921 be increased from \$8,000,000 to \$10,000,000.

The estimate for \$8,000,000 was made last August by the Surgeon-General and at that time it was thought it would be sufficient for the purpose, but since that time the number of patients has greatly increased and it has been found necessary to ask Congress for \$10,000,000 to take care of this increased number of patients during the present fiscal year. The sum of \$6,000,000 has already been appropriated, and the second urgency deficiency bill contains an item for the provision of an additional \$4,000,000. There was a deficiency of \$246,000 on Feb. 1, 1920, so that the whole of this additional \$4,000,000 will undoubtedly be needed.

In view of the above fact, I ask that Congress be requested to grant this additional \$2,000,000, in order that the sick and disabled discharged persons from the military and naval forces may be given proper care and treatment during the fiscal year 1921.

Respectfully,

J. C. PERRY,

Acting Surgeon-General, U. S. Public Health Service.

MEDICAL OFFICERS, U. S. NAVY, RELIEVED FROM ACTIVE DUTY

CALIFORNIA

PARIS

March 4, 1920.

Meeting of French Medical Journalists

The general meeting of the Association professionnelle des journalistes médicaux français was held recently at the Faculté de médecine de Paris under the presidency of Dr. Doumer, professor at the Faculté de médecine de Lille.

After the reading of the reports of the general secretary and treasurer, the assembly adopted the following code of ethics: 1. The members of the association shall afford each other mutual aid. 2. No members of the association shall agree to do the work of a colleague for less money than such colleague received. 3. A member of the association shall not accept the position of a colleague without having first informed such colleague and having learned the latter's reasons for leaving the position. 4. If a member of the association is appointed managing editor of a journal, or is requested to choose the members of the editorial staff, he shall give preference to the members of the association. 5. If the relative merit of articles by members of the association is the same as that of others, preference should be given to members of the association in the matter of abstracts and personal mention. 6. Members of the association will mention, whenever possible, the works of the association and of its individual members, and the events concerning the members of the association, in the journals on which they col-

laborate. 7. Every case at law between two members of the association shall be first taken up and discussed by the family council of the association before it is brought before any other jurisdiction. 8. In the case of litigation of a professional nature between a member of the association and an outsider, the association shall examine into the cause, and if it shall recognize the justice of its member's case, it shall give him its moral support, and, if the circumstances seem to warrant it, such financial assistance as may seem proper; and if it shall decide on such a course it shall hold a special meeting to decide what aid shall be given the members in question. 9. The foregoing articles must be accepted by every applicant for membership in the association.

The Crowded Condition of Paris Hospitals

During the war, the mobilization of a large number of physicians made it necessary for many people to have recourse to the hospital who could otherwise have been cared for at home. This circumstance gave them an opportunity of discovering that the hospitals, from the standpoint of medical skill, care and hygiene, offered all that could be expected. All classes of Paris society thus came in contact with the consultation service afforded by the hospitals. They learned that in the hospital one is better cared for than anywhere else, and also that such care does not cost them a sou. Consequently, they have continued to rely on the hospital, and the deplorable result has been that there is no longer sufficient room in the hospitals for the really needy.

The maternity hospitals are especially crowded. In order to remedy this condition, the prefect of the department of the Seine has adopted a series of measures with the view of giving special aid to women who will consent to be confined at home, such as the assumption by charitable organizations of the fee charged by midwives and the fixing of the ordinary medical fee at 20 francs a visit. Furthermore, M. Mesureur, director of the Assistance publique, has announced that he has been able to provide 300 more beds for confinement cases.

Number of Wounded Still Under Treatment in the Military Hospitals

In reply to a request for information received from a member of the Chamber of Deputies, the minister of war states that the number of demobilized wounded soldiers and sailors still under treatment in the military hospitals, under date of Jan. 15, 1920, was 7,133.

Measures to Promote an Increase in the Birth Rate

Adolphe Chéron, deputy of the department of the Seine, has presented a bill which is intended to promote an increase in the birth rate. Among the measures proposed I may mention the surveillance of lying-in hospitals; the repression of abortion and birth control, relieving physicians and midwives, under certain circumstances, from the obligations of professional secrecy, and aid to large-sized families.

Reorganization of Night Medical Service

In a previous letter (THE JOURNAL, March 20, 1920, p. 815), I referred to the reorganization of night medical service in Paris. The Syndicat des médecins of the department of the Seine, which had offered to take part in the competitive examination held in connection with the reorganization of this service, is protesting vigorously because the proffered collaboration of the Syndicat was systematically ignored by the administration.

Typhus Fever in Paris

A slight epidemic of typhus fever has been reported in the Saint-Sulpice seminary, where refugees have been lodged; among others, a number of Polish workmen. The epidemic seems now to have been brought to an end. The Assistance publique has given instructions that delousing in the hospitals shall be done with great care. In this connection, Senator Gaudin has asked the minister of hygiene what measures have been taken to protect France against typhus fever, which is raging in Poland and the Ukraine. The minister of hygiene has replied that, according to the most recent information, there is no epidemic of typhus fever in the countries of central Europe immediately contiguous to our borders. There were a few sporadic cases in Germany, but this did not constitute a menace to us. In Poland, however, it was true that an epidemic existed. There was danger of its being brought to France by emigrant Polish workmen if strict measures to prevent it were not taken. Besides the prophylactic measures taken in Poland when the workmen leave there, vigorous sanitary measures are carried out by the bureau of immigration when they arrive in Toul, which is especially,

or one may say, exclusively, affected by Polish immigration. Owing to an understanding reached by the civil and military sanitary authorities, the bureau of immigration at Toul is abundantly provided with the necessary sanitary apparatus. The prophylactic measures taken consist of a medical examination, vaccination, shower baths, disinfection, disinfection, and isolation of suspects.

Increase in Medical Fees

Owing to the increased cost of living, medical fees in Paris have been doubled. The Syndicat médical of Montpellier has gone even further and has decided to triple former rates, the fee for a simple office consultation being 15 francs; emergency calls or consultations on Sundays and holidays, 30 francs; night calls, 50 francs; special distance charge, 3 francs per kilometer. The foregoing rates represent the ordinary charges and do not affect famous consulting physicians nor specialists.

LONDON

Feb. 28, 1920.

Incidence of Influenza

The Ministry of Health has issued a long circular on influenza, stating that the disease is epidemic in many large American cities, but the proportion of severe or fatal cases is smaller than in 1918-1919. Our vital statistics show a slight increase, but the increments are so small and the uncertainty of classification so great that no unfavorable inferences can be drawn from these fluctuations. Notified pneumonia has increased, but here again it is not possible to say how much of this may be due to seasonal variations. There are no indications of epidemic influenza in factories, but some large schools in southern and southwestern England are affected. The disease is epidemic in a few localized communities, and the type is similar but less severe than that of 1918-1919. There is no evidence of a pandemic comparable to that occurring in America and certain parts of Europe. The ministry again draws attention to the warning previously given and the measures advised (as referred to in previous letters).

Reconstructing the Army

Many bitter complaints have been made of the obstruction to urgently required reforms offered by the higher command of the army, perhaps the most conservative body among a conservative people. But, above all, we are practical, and can learn in the dear school of experience. So the reformers had their way in the end, and the British army became as perfect and as modern a fighting machine as it was possible to make. There is now no backwardness in profiting by the lessons of the war. The war office has issued a memorandum showing how these have been applied in every branch of the service. The prewar establishment of officers of the medical corps was 1,068. On the date of the armistice the strength of officers was 14,461, and in addition 1,524 civil physicians were employed. There are at present employed 3,338 officers and 322 civil physicians, and this number is continually being reduced in conformity with the reduction in hospital population. The prewar establishment of other ranks was 3,895. The strength of warrant officers, noncommissioned officers and men of the medical corps on the date of the armistice was 131,361. This number was supplemented by the employment of 18,660 voluntary aid detachment, general service women in hospitals, and other formations in the United Kingdom, while large numbers of such women were also employed in France, Saloniki and Malta. The strength of other ranks, Feb. 8, 1920, was 18,412. There were in addition, employed in hospitals, etc., in the United Kingdom 4,771 voluntary aid detachment, general service women. Considerable numbers of the latter are still being employed in the Rhine army, Black Sea, and Malta. The medical section of the territorial army will be reorganized on its prewar basis, with such additions and alterations as the war has shown to be necessary.

DENTAL CORPS

Sound teeth in the soldier are of prime importance. An army dentally fit will have reduced rates of sickness and invaliding. A proposal has therefore been put forward for the formation of a dental corps to consist of 110 officers and 132 of other ranks (mechanics and orderlies) for which it is hoped approval will be obtained.

PATHOLOGY AND HYGIENE

New directorates of hygiene and pathology have been established within the army medical department, each with a director and deputy at headquarters, and assistants and deputy assistants in the important commands and districts at

home and abroad. It will now be possible for officers who have devoted their professional lives to the study and practice of these highly technical subjects to continue to work in them throughout their service, instead of, as has hitherto been the case, having to abandon them to take up ordinary administrative duties on attaining a certain seniority. Promotion to the highest rank is now open to such specialists.

VACCINE DEPARTMENT AT THE ARMY MEDICAL COLLEGE

The work of the vaccine department during the war developed enormously. More than 33,000,000 doses of vaccines against typhoid, cholera, dysentery and other conditions were prepared during the last five years and dispatched for the use of troops serving in all parts of the world. Among our great armies in France, from the beginning of the war till the end of 1918, there were only 7,423 cases of typhoid and paratyphoid, with 266 deaths. In the much smaller Boer War there were 57,684 cases, with 8,022 deaths. In the French army, before it was fully protected by inoculation, there were, from the commencement of hostilities till the end of October, 1915, 95,809 cases, with 11,690 deaths. Subsequent to that period their figures are more comparable with our own. Recent German statistics of mortality in their armies during the war mention 7,751 deaths from typhoid.

HOSPITAL ACCOMMODATION IN THE UNITED KINGDOM

The total number of beds of all kinds at the armistice was 364,133; Feb. 6, 1920, 43,497; the number closed since the armistice has been 320,636. The numbers in hospitals in the United Kingdom at the time of the armistice were 316,000; May 1, 1919, 112,000; Feb. 1, 1920, 28,000. At the time of the armistice there were also 8,619 patients on special leave, and 4,648 in billets. These were slightly ill or convalescing patients who were disposed of in this way owing to the pressure on the hospital accommodation.

CHEMICAL WARFARE

We must unfortunately continue our studies of what is known as chemical warfare. No nation has renounced the use of poison gases as the result of the peace conference. There are nations whose word we could not respect if they did renounce it. It is essential to study the offensive side of chemical warfare if we are to be prepared for defense. The great importance of adequate defensive appliances arises from the fact that preparations for the offensive use of gas can be made in peace time with great secrecy, and may have far reaching and even fatal results in the early stages of war.

Eugenics

At the Galton anniversary, Arthur Keith delivered the lecture. He said that while Charles Darwin, who was Galton's cousin, and those who championed the cause of evolution turned their attention to unveiling man's past, Sir Francis Galton devoted his life and genius to discover how the machinery of evolution which had raised man to his present estate could be used for his further advancement. Galton discovered the ladder whereby, if a nation were so minded, it could climb to a higher estate of both mind and body. The rungs of that ladder he fashioned out of the laws of heredity. Under nature's conditions, and amid the circumstances of modern life, we tried to climb blindly, and we stumbled, fell and suffered. Galton showed that the ascent could be made sure, easy and merciful. In his earlier days he was, perhaps, inclined to invoke the aid of the state and to resort to compulsory measures; but, as his knowledge grew and his experience ripened, he realized that mere artifices invented by statesmen could affect only the stragglers on the ladder—the main mass of the nation would be left untouched. The nation which would raise itself on the ladder must raise itself not piecemeal, but as a whole; every grade and section of a people must be made to move upward at the same time. Galton saw that to effect such a desirable change—one which would give the nation which adopted it an advantage over all its neighbors or rivals—the heart of the people must first be captured and a social avalanche set in motion. He was convinced that if a knowledge of his ideals, his aims and his discoveries could be made to sink into and leaven the minds of the people, the upward movement he longed to initiate would at length begin. That could be done only by education—education in the laws which govern the transmission and building up of the best qualities of the brain and body.

Removal of a Children's Hospital to the Country

The importance of country life to the sick is becoming more and more recognized. Though many hospitals maintain convalescent homes in the country, it has not happened

before that a hospital has been moved bodily to the country. This has been done in the case of the Alexandria Hospital for Children with Hip Disease, an institution established in London many years ago.

Threatened Strike of Physicians

The tendency of a portion of the profession to adopt militant labor methods has been shown by the formation of the Medico-Political Union, a body registered as a trade union which, however, has not been able to attract more than a few members. Another example of the tendency has occurred in Ireland. The physicians in the Castle Comer Union have threatened to strike unless the guardians accede to their demand for increased salaries. At a large meeting of physicians in the neighboring town of Kilkenny, a resolution was passed expressing sympathy with these medical officers in their determination to cease work and refuse to attend any patient until their demands are acceded to. Medical trade unionists in England have not gone this length, for they have always explained that they have no intention of striking against the sick, but merely against working for the state when the terms are unsatisfactory, so that in case of a dispute their services would be available, though not under government arrangements.

BUENOS AIRES

Feb. 18, 1920.

Visit of Drs. Mayo and Martin

From February 4 to 8 Drs. W. J. Mayo and F. H. Martin, who came here from Chile, and went afterwards to Montevideo, were in Buenos Aires. Their trip had for its object to cultivate closer relations between the American College of Surgeons and the surgeons of South America. The School of Medicine of Buenos Aires designated Professors Arce, Chutro, Viñas and Palma to accompany our guests, who, while they were here, made a rather rapid survey of four of the local hospitals. While at Buenos Aires, Dr. Mayo called attention to the poor organization of the nurses' service in the municipal hospitals and the inadequate protection against flies.

Typhus Fever in Chile

In connection with several articles by Argentine physicians, the director-general of public health of Chile, Dr. Ramon Corvalán Melgarejo has published a report on the present epidemic of typhus fever. There are no cases of the disease in the northern provinces as far as Aconcagua, the disease having disappeared from Andes, Limache, Calera, San Antonio, La Victoria, Rengo, Peumo, San Carlos, Yungay, Florida, Coronel, Temuco and Conbarbala. There has been a recurrence of the epidemic at Valparaíso, with more than 160 cases. At San Fernando, Cunaco, Concepción, Talcahuano, Cabrero, Mulchen and Imperial the epidemic has decreased very much. At Santiago there were at one time as many as 580 hospital cases with an average of thirty-four cases a day, but the epidemic there has also decreased very much, there being now only 163 hospital cases with an average of ten new patients a day.

The enforcement of preventive measures, similar to those adopted last year, on the railroad station at the frontier, has been recommended to the National Department of Public Health.

Bubonic Plague

The increase of plague in all South American countries has also revealed itself in Argentina. The National Department of Public Health has put in force deratization measures at Buenos Aires, and has decided to establish disinfection stations in all the ports of the republic. The province of Santa Fe, which has suffered most from the disease, has been divided into three zones with headquarters at Santa Fe, Cordoba and Casilda, in charge, respectively of Drs. Ruiz Huidobro, Beuchettil, and Bascary, who will carry out anti-rat measures throughout that district.

Marriages

HERBERT RANDOLPH UNSWORTH to Miss Elizabeth Elmer McCall, both of New Orleans, March 12.

THOMAS LAWTON, Hinsdale, Ill., to Miss Elizabeth A. Stage of Davenport, Iowa, March 16.

EDGAR CHRISTY, Hastings, Iowa, to Mrs. Elsa Riedelsberger, at Omaha, March 3.

Deaths

Philip Coombs Knapp, Boston; Harvard Medical School, 1883; aged 61; a member of the American Urological Association and its president in 1895, and a specialist in neuropathology; a fellow of the Royal Society of Medicine; visiting physician to the division of nervous diseases of the Boston City Hospital since 1885, and to the Boston Dispensary from 1886 to 1888; instructor in diseases of the nervous system in his alma mater from 1888 to 1913; consulting physician to the Massachusetts State Hospital for Insane Criminals since 1895; trustee of the Boston Insane Hospital from 1897 to 1902; died in the Boston City Hospital, February 22.

Clinton Tremaine Purdy, Moncton, N. B.; University of the City of New York, 1884; aged 60; formerly mayor of Moncton; coroner of Westmoreland County in 1897; president of the Moncton Medical Society in 1898; formerly president of the College of Physicians and Surgeons of New Brunswick; a member of the medical council of New Brunswick and alderman for the city of Moncton; died, January 12.

Richard Henry Lee Bibb * Saltillo, Coahuila, Mexico; Texas Medical College, Galveston, 1872; Bellevue Hospital Medical College, 1877; aged 71; for many years chief surgeon of the Mexican National Railroad, of the American Hospital, Mexico City, and of the national lines of Mexico; president of the International Medical Association of Mexico in 1911; died, March 2, from influenza.

Emile Schmoll, Livermore, Calif.; University of Basle, Switzerland, 1896; aged 47; a member of the Medical Society of the State of California; lecturer on internal medicine in Cooper Medical College and visiting physician of the San Francisco City and County Hospital; died, March 10, at a sanatorium in Livermore, from a nervous breakdown.

William Charles Hassler * San Francisco; Cooper Medical College, San Francisco, 1892; aged 51; health officer of San Francisco; a specialist in public health; assistant professor of hygiene and sanitary science in Hahnemann Medical College of the Pacific, San Francisco; died, February 11, from influenza.

Wade Doster, Capt., M. C., U. S. Army, Coldwater, Kan.; Jefferson Medical College, 1907; aged 39; on duty at Camp Furlong, N. M.; was shot and killed by his wife at Columbus, N. M., March 9, while she was defending herself from an attack made by him, in which she received a bullet wound of the breast.

Charles Sackett Starr, Rochester, N. Y.; College of Physicians and Surgeons in the City of New York, 1869; aged 75; a member of the Medical Society of the State of New York; physician to the Monroe County Jail in 1879 and 1880, and coroner's physician from 1880 to 1884; died, March 8.

Henry Wells Horn * San Francisco; Cooper Medical College, San Francisco, 1897; aged 48; a member of the American Ophthalmological, Rhinological and Otological Society; a well known ear, nose and throat specialist; died in St. Francis' Hospital, March 5, from influenza.

Hugo William Wightman * Scottsbluff, Neb.; Northwestern University Medical School, Chicago, 1901; aged 47; for ten years professor of anatomy in the John A. Creighton University, Omaha; surgeon to the Brazil Hospital; died in a hospital in Omaha, March 11, from influenza.

George W. Simpson, Mapleton, Pa.; Jefferson Medical College, 1876; aged 75; a member of the Medical Society of the State of Pennsylvania; for ten years local surgeon to the Pennsylvania system; a veteran of the Civil War; died in his apartment, March 6.

Henry Howard Wynne, Oklahoma City; College of Physicians and Surgeons in the City of New York, 1880; aged 60; a member of the Oklahoma State Medical Association; a specialist on diseases of the eye, ear, nose and throat; died about February 26.

Stafford Baker Smith * New York City; College of Physicians and Surgeons in the City of New York, 1905; aged 36; a member of the American Urological Association; surgeon, U. S. P. H. S.; died, February 29, from lobar pneumonia.

Benton Knox Jones, Kenton, Ohio; Eclectic Medical Institute, Cincinnati, 1889; aged 62; president of the Ohio State Medical Association in 1897, and for two terms coroner of Hardin County; died, March 6, from erysipelas.

Angus McD. Ford, Montreal; Bishop's College, Montreal, 1898; F.R.C.S., L.R.C.P. (Edin.), who had been on military duty with the Canadian Army Medical Corps since the beginning of the World War; died at sea, recently.

Herbert James Hamilton, Toronto; University of Toronto, 1886; L.R.C.P. (Lond.), 1886; aged 55; once president of the Ontario Medical Association; died in Wallerley Hospital, Toronto, from pneumonia, February 5.

Townsend F. Dickinson, Cincinnati; Miami Medical College, Cincinnati, 1881; aged 61; president of the Cincinnati Pension Examining Board during President Cleveland's administration; died, March 5.

Derrick G. Barkalow, Adel, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1884; aged 62; once president of the Dallas County Medical Society; died about March 5, from cerebral hemorrhage.

Joseph Alexander Gendron, Ware, Mass.; Victoria University, Cobourg, Ont., 1888; aged 57; for several terms a member of the board of health of Ware; died in the Ware Hospital, March 7.

Edgar D. Seaman, Los Angeles; College of Physicians and Surgeons in the City of New York, 1884; aged 64; a member of the Medical Society of the State of California; died, February 20.

Donald Hoff Hoover, Cleveland; Western Reserve University, Cleveland, 1919; aged 26; an intern in the Lakeside Hospital, Cleveland; died in that institution, March 2, from pneumonia.

John Alva Allen, Medical Lake, Wash.; Trinity Medical College, Toronto, 1904; aged 42; captain, M. C., U. S. Army, and discharged, March 3, 1919; died, March 5, from pneumonia.

Abraham Lincoln Garver, Roaring Spring, Pa.; Jefferson Medical College, 1883; aged 61; a member of the State Industrial Board since 1916; died, March 2, from angina pectoris.

Charles Richard MacKimmie, Norfolk, Va.; Maryland Medical College, Baltimore, 1903; aged 51; died, February 12, from disease of the stomach and liver following influenza.

John J. McCarthy, Williamsport, Pa.; College of Physicians and Surgeons, Baltimore, 1896; died in the Renovo, Pa., Hospital, March 5, from pneumonia following influenza.

William Wickham Horton, Unionville, Conn.; University of the City of New York, 1879; aged 64; a member of the Connecticut State Medical Society; died, February 19.

Robert Joseph Dwyer, Toronto; University of Toronto, Ont., 1891; M.R.C.P. (Lond.), 1902; associate professor of clinical medicine in his alma mater; died, January 26.

Lachlin MacPherson, Antigonish, N. S.; Tuft's College Medical School, Boston, 1907; aged 44; died in St. Martha's Hospital, Antigonish, January 1, from pneumonia.

Sheldon B. Hewett * Girard, Kan.; University Medical College of Kansas City, Mo., 1904; aged 42; died, February 26, from cardiac embolism following influenza.

Edward S. Quinn, Kirksville, Mo.; Marion-Sims Medical College, St. Louis, 1896; aged 59; a member of the Missouri State Medical Association; died, February 24.

David Jenkins McCaa, Ephrata, Pa.; Jefferson Medical College, 1867; aged 74; died, March 10, from injuries received in a runaway accident in February.

Sam W. Adams, Rockland, Texas; University of Memphis, Tenn., 1894; aged 53; died in the Hotel Dieu, Beaumont, Texas, February 16, from septic meningitis.

Robert Kirkwood Robinson, Belair, Md.; University of Maryland, Baltimore, 1859; aged 87; a veteran of the Civil War; died, March 9, from senile debility.

James M. Robinson * Guthrie, Ky.; University of Louisville, Ky., 1882; aged 64; once mayor of Guthrie; died, February 26, from carcinoma of the stomach.

Henry A. Phillips, Chicago; Bennett Medical College, 1871; aged 75; a member of the Illinois State Medical Society; died, March 7, from pneumonia.

Abram Markle Blackburn, Steubenville, Ohio; Medical College of Ohio, Cincinnati, 1864; aged 77; a veteran of the Civil War; died, March 5, from uremia.

Peter Lafayette Adams, Dawson, Texas; St. Louis College of Physicians and Surgeons, 1898; aged 77; died at the home of his daughter in Dawson, February 9.

Albert Harris Daniels, Mitchell, S. D.; University of Michigan, Ann Arbor, 1864; aged 79; for thirty-four years a practitioner of Mitchell; died, March 4.

* Indicates "Fellow" of the American Medical Association.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

PLATT'S CHLORIDES

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report on "Platt's Chlorides." It also declares the preparation inadmissible to New and Nonofficial Remedies because its composition is uncertain and indefinite and because the claims made for it are exaggerated and misleading.

W. A. PUCKNER, Secretary.

"Platt's Chlorides," marketed by Henry B. Platt, New York, is sold as a disinfectant and germicide. Only incomplete and contradictory statements have been made in regard to its composition. Many years ago (about 1899) the composition of Platt's Chlorides was given as "The Chlorides of Zn 40 per cent., Pb 20, Ca 15, Al 15, Mg 5, K 5." The statement that the preparation contained 20 per cent. of lead chlorid, is interesting in view of the fact that lead chlorid is soluble in water at ordinary temperatures to the extent of less than one per cent. In a booklet, also issued a number of years ago, the following "Formula of Platt's Chlorides" was given:

"A saturated solution of Metallic Chlorids combined in the following proportions:

"Sol. Zinc Chlorid	40 per cent.
"Sol. Aluminum Chlorid	15 per cent.
"Sol. Lead Chlorid	20 per cent.
"Sol. Calcium Chlorid	15 per cent.
"Sol. Magnesium Chlorid.....	5 per cent.
"Sol. Potassium Chlorid	5 per cent."

The label on a bottle purchased in 1911, describes Platt's Chlorides as:

"A Highly Concentrated Solution of the Chlorids of Aluminum, Calcium, Lead, Zinc, etc."

The label of a bottle purchased in 1919, reads:

"Contains Inert Material: Water 84.0%. Sodium Chlorid 4.8%. Calcium Chlorid 0.3%."

This statement is obviously made to meet the requirements of the federal Insecticide Act. This law requires either that the identity and the amounts of potent ingredients in disinfecting preparations be declared or else that the percentage of the inert ingredients of such preparations be given. The omission from the label of all statements with regard to the potent ingredients of the preparation and the absence of such a statement in recent advertising matter suggests either that the older statements about its composition were false or else that the composition has been changed.

Tscheppe published (Pharmaceutische Rundschau 8:109, 1890) an analysis of Platt's Chlorides which has been quoted in other publications as indicating the composition of the preparation. He reported that he found each quart of the preparation to contain aluminum sulphate 6 ounces, zinc chlorid 1½ ounces, sodium chlorid 2 ounces, calcium chlorid 3 ounces.

Some years ago (about 1911) the company made the following statement relative to the germicidal power (phenol co-efficient) of Platt's Chlorides:

"... for some time the carbolic acid co-efficiency of our output has been from 2.5 to 4.3; the average being about 3; namely about three times stronger than pure carbolic acid."

In 1912, the U. S. Public Health and Marine Hospital Service reported (*Bulletin 82*, Public Health and Marine Hospital Service, p. 69) that the phenol coefficient of a sample of Platt's Chlorides was so low that it could not be determined and also that the sample was found to contain some mercuric chlorid. In 1913, the North Dakota Agricultural Experiment Station reported (*Bulletin*, July, 1913, p. 292), that

William John Chambers, Calgary, Alta.; University of Toronto, Ont., 1902; was instantly killed in a railway accident at Sudbury, Ont., recently.

William Edward Everett, Brownsburg, Ind.; University of Michigan, Ann Arbor, 1869; aged 74; died, February 16, from pneumonia following influenza.

James R. Adams, Fort Worth, Texas; Medical College of Ohio, Cincinnati, 1841; aged 97; died at the home of his son in Fort Worth, February 27.

James Patrick Lane ☉ Cascade, Iowa; John A. Creighton Medical College, Omaha, 1906; aged 40; died in Mercy Hospital, Dubuque, February 29.

David H. Clay Scott, Montgomery, Ala.; Meharry Medical College, Nashville, Tenn., 1895; aged 49; died, Dec. 25, 1919, from carcinoma of the liver.

Charles Baker Reid ☉ Van Wert, Ohio; Fort Wayne, Ind., College of Medicine, 1881; aged 63; died, March 1, from cerebral hemorrhage.

Osmund Eells Goodrich, St. Joseph, Mich.; Hahnemann Medical College, Chicago, 1866; aged 75; died, February 27, from senile debility.

Almon L. Brown ☉ Milwaukee; Rush Medical College, 1894; aged 54; a specialist in internal medicine; died, Dec. 1, 1919, from diabetes.

Joseph Mickler, Tampa, Fla.; University of Tennessee, Nashville, 1914; aged 33; a roentgenologist; died, March 5, from typhoid fever.

James Polk Von Stein, North Liberty, Iowa (license, years of practice, Iowa, 1887); aged 68; a practitioner since 1877; died, March 1.

James Edward Harper, Assumption, Ill.; Chicago Homoeopathic Medical College, 1899; aged 50; died, February 21, from sarcoma.

Russell Hathaway, Wellington, Ohio; Homeopathic Hospital College, Cleveland, 1876; aged 72; died, February 27, from neuritis.

John H. MacDonald, Chicago; Jenner Medical College, 1898; aged 64; died, March 16, from carcinoma of the mouth and throat.

Louis William Knight, Baltimore; University of Maryland, Baltimore, 1866; aged 75; a noted numismatist; died, March 16.

James Louis Gilbert, El Paso, Texas; Baylor University, Dallas, Texas, 1911; aged 33; died, February 20, from influenza.

Louis E. H. Duffel, Napoleonville, La.; Tulane University, New Orleans, 1900; aged 44; died in New Orleans, February 28.

Edward Gomer Davies, Yankton, S. D.; Rush Medical College, 1879; aged 74; died, March 8, from valvular heart disease.

John T. McGrath, Scranton, Pa.; University of Pennsylvania, Philadelphia, 1896; aged 45; died, March 4, from heart disease.

William J. Brand, Detroit; University of Buffalo, N. Y., 1886; aged 63; died, February 29, from locomotor ataxia.

Warrick Barnett, Borden, Ind.; University of Louisville, Ky., 1911; aged 37; died, February 8, from pneumonia.

James C. Fish ☉ Beaver Falls, Pa.; Jefferson Medical College, 1884; aged 58; died, March 1, from pneumonia.

Charles Naylor Abbott, McKinnie, Texas; University of Alabama, Mobile, 1875; aged 69; died, February 20.

Charles W. Tower, Marshfield, Ore.; Willamette University, Salem, Ore., 1870; aged 79; died, February 26.

John Abram Hunt, Taunton, Mass.; Boston University, 1893; aged 65; died, February 13, from carcinoma.

Oscar M. Waterman, San Francisco; University of Leipzig, Germany, 1893; aged 63; died, February 27.

Edward F. Christian ☉ LaCrosse, Wis.; Rush Medical College, 1906; aged 36; died, February 25.

Joseph M. Ferguson, Sedalia, Mo.; University of Louisville, Ky., 1869; aged 80; died, March 6.

Correction.—Dr. Guy Marshall McDowell, Bay City, Mich., advises us that, notwithstanding the notice of his death which appeared in THE JOURNAL, March 13, he is "still alive and going strong." The Dr. McDowell who died was Dr. Guy McDowell who formerly lived in Bay City, but had been practicing in Detroit for about twenty years.

Platt's Chlorides contained principally zinc chlorid, also some aluminum chlorid, calcium chlorid, and traces of mercuric chlorid. The phenol coefficient, determined by the Hygienic Laboratory method, was found to be 0.05.

The preceding suggests that the composition of Platt's Chlorides had been changed (without notice to the consumer) and that it had been fortified by the addition of mercuric chlorid. Years ago part of the advertising of this product was a testimonial from a health official which declared that, for disinfection, "bichlorid of mercury is useless in disinfecting sputum or discharges from the bowels, being rendered inert by the albumen present" and it lauded Platt's Chlorides as devoid of such drawbacks.

RECENT ANALYSES OF PLATT'S CHLORIDES

To determine the present composition of Platt's Chlorides and to compare it with that sold formerly, the A. M. A. Chemical Laboratory has made an analysis of a specimen purchased in 1919 and also of one that was purchased in 1911 and since kept unopened in the files of the Council on Pharmacy and Chemistry. The following table contains the results of these analyses (all quantities given are Gm. per 100 c.c.):

	1911 SPECIMEN	1919 SPECIMEN
Color	Colorless	Straw Color
Odor	None	None
Specific Gravity at 25 Cc.	1.1229	1.1313
Total Solids (residue at 100 Cc.)	16.49	18.33
Chlorid (Cl-)	7.60	10.74
Sulphate (SO ₄ --)	1.11	.16
Aluminum (Al+++).22	.90
Calcium (Ca++)19	.13
Zinc (Zn++)	5.11	3.93
Lead (Pb++)046	Traces
Mercury (Hg++)0086
Sodium (Na+)	1.01	1.39

These quantities transposed to hypothetical combinations would indicate that Platt's Chlorides has the following composition:

	1911 SPECIMEN	1919 SPECIMEN
Aluminum Sulphate	1.32	.18
Aluminum Chlorid07	4.29
Calcium Chlorid54	.37
Zinc Chlorid	10.66	8.19
Lead Chlorid06	Traces
Mercury Chlorid0116
Sodium Chlorid	2.57	4.81
Hydrogen Chlorid43	None

In the past, the advertising has suggested, more or less directly, that, as chlorinated lime (bleaching powder) may be made to give off chlorin gas which disinfects, so the air in a room may be disinfected by evaporating Platt's Chlorides. Thus the label of the 1911 specimen contains the following:

"FOR STORE ROOMS, Refrigerators, and Closets, keep a sponge saturated with the pure liquid in a saucer on an upper shelf."

On the label of the 1919 specimen, the statement reads:

"REFRIGERATORS AND STOREROOMS—As a disinfectant wash regularly with one part Chlorides to eight of water. As a deodorant, keep in an open vessel a sponge or cloth saturated with the Chlorides full strength."

That the owner of Platt's Chlorides really believes that the vapors of the preparation have disinfecting properties is seen from a letter over the name of Henry B. Platt printed in the New York *Tribune* in 1916. This read, in part:

"... by keeping in a dish or saucer on radiators Platt's Chlorides diluted one-half, the hot solution will evaporate and purify the air, thus destroying the grip germ which is the cause of all the trouble."

From the analysis of Platt's Chlorides, it is evident that when the preparation is evaporated, water vapor only escapes.¹

1. It is well known that when a solution of mercuric chlorid in water is evaporated, mercuric chlorid passes off with the water vapors, but under any condition the amount is but a fraction of the whole. As in Platt's Chlorides other metallic chlorides are present, the formation of complex mercuric compounds which is bound to have occurred, should retard or prevent the volatilization of mercuric chlorid. That this actually occurs was confirmed by the following experiment: When 1 gm. mercuric chlorid was dissolved in 1 liter of water and the solution distilled, the distillate contained a very small amount of mercury. Then the experiment was repeated after adding sodium chlorid to the solution to simulate the conditions in Platt's Chlorides. In this case no mercury was found in the distillate. Even were all the mercury in a bottle of Platt's Chlorides volatilized in a room 10 by 12 by 9 feet, this would be equivalent to only about $\frac{1}{100}$ grain mercuric chlorid per cubic foot.

Whatever disinfecting or germicidal action the preparation may possess is exercised only when the solution is brought in direct contact with the substance to be disinfected.

The aluminum and zinc salts present may be useful as deodorants but they are not effective as germicides. The presence of mercuric chlorid in a concentration of 1 to 10,000 is hardly to be considered as materially increasing the efficiency. The directions recommend the use of a mixture of 1 part of Platt's Chlorides to 10 parts of water for rinsing the hands, and a mixture of 1 part to 4 parts of water for the disinfection of discharges. It is further stated that 1 quart makes 2 gallons sufficiently strong for general use. It is evident that such dilutions decrease considerably the feeble germicidal action of the original fluid.

Correspondence

"GOLAY'S MODIFIED WASSERMANN REACTION"

To the Editor:—In the description in Queries and Minor Notes of the Golay modification of the Wassermann reaction (THE JOURNAL, Feb. 21, 1920, p. 543) you say the "complement is obtained from a rabbit." I take it that this is an error and should be "amboceptor." In the titration of the amboceptor I presume a known negative active human serum is used. It is this feature that has attracted my attention. The hemolytic factor is completed with the active native human complement. In a series of experiments over a period of ten months I have found that the quantity of human complement varies in different individuals, and in some it is absent. The estimation of the quantity of complement in a given serum is based in general on the Hecht modification of the Wassermann reaction, with modification of details adaptable to the human system. The reagents used were 2.5 per cent. human red cell suspension, one unit of amboceptor, and beef heart antigen cholesterinized to the extent of 0.072 per cent. in dilutions of 1:10. The serum to be tested should be fresh, but I have found complement still active after traveling 400 miles in the mail in moderately warm weather.

To determine the complementary value of a serum, six tubes are set up in the front row. Each tube receives 0.1 c.c. of active serum and one unit of amboceptor. The first receives 1 c.c. of salt solution, and each succeeding tube 0.1 c.c. less than the preceding tube. In the first tube is placed 0.1 c.c. of human red cells, and in each succeeding tube 0.1 c.c. more, so that the last tube will receive 0.6 c.c. of cells. These tubes are then incubated for one hour at 37 C., during which time they are repeatedly shaken. At the end of this period that tube is sought in which there is the greatest amount of complete hemolysis. If the last tube shows complete hemolysis, which rarely happens, 0.3 c.c. is used in the actual test for that particular serum. Two rear tubes are set up at the time the series of six are prepared; one receives 0.1 c.c. of the same active serum, 0.1 c.c. of antigen, and 0.7 c.c. of salt solution; the other tube receives 0.1 c.c. of serum and 0.8 c.c. of salt solution; both are then placed in the refrigerator for a period of three or four hours. At the end of that period these tubes receive the required amount of red cells, one unit of amboceptor and salt solution to 1.3 c.c. If the particular serum contains sufficient complement to hemolyze 0.6 c.c. of cells so that 0.3 c.c. is used in the test, no salt solution is added. The control tube always clears. If the maximum amount of cells is used as determined in the series, for instance, 0.6 c.c., the control tube often will not clear with negative serum. If complete hemolysis does not occur in any of the series of tubes, it signifies no complement.

My purpose of describing this test is to state that it is unsatisfactory as compared with the Wassermann reaction, using the antihuman system. When applied in this manner the human complement apparently is not as easily fixed as is the guinea-pig complement as used in the Wassermann reaction. The use of guinea-pig red blood cells to determine the

hemolytic index of human serum, and with this means determine the syphilitic factor of the serum, gives a much higher percentage of positive results than the test described above, but the guinea-pig system does not give any higher percentage of positive results than the Wassermann using the antihuman system.

JOHN FUNKÉ, M.D., Atlanta, Ga.

LOW TYPHOID DEATH RATE OF RICHMOND, VA.

To the Editor:—I wish to express my gratification in connection with what you have to say concerning Richmond's 1919 typhoid record (*THE JOURNAL*, March 6, 1920, p. 672). I am glad that you agree that our rate of 3.7 is quite an extraordinary one for a Southern city.

It is gratifying to see in Table 6 that Richmond is the only city south of the Potomac and Ohio rivers appearing in the first rank, and that even those Southern cities which appear in the second rank come in at the tail end, while the third rank and fourth rank are composed entirely of Southern cities. In other words, if the cities of over 100,000 population are ranged in the order of their typhoid death rates, Southern cities, with the exception of Richmond, are found entirely at the bottom.

Your statement that "it is evident that the maintenance of a low typhoid death rate is not to be taken as a matter of course without the exertion of constant vigilance by the local health authorities" is certainly true. I know that in the case of Richmond our constantly decreasing rate has been due to constant effort and watchfulness. This year we shall have a hard job holding down to last year, and, in fact, there is little, if any, chance of our duplicating our 1919 rate. Unfortunately, our first three cases this year all terminated fatally, and besides this, we have had one more death, so that, although only seven cases have been reported this year, we have already had four deaths, against a total of six in 1919.

As an illustration of the desire on our part to have accuracy at all cost, I may state that the death certificate in the case last mentioned came in to us with influenza and septicemia given as the cause of death. The blood specimen taken on the last day of illness, however, showed the presence of the typhoid bacillus. We had considerable difficulty in persuading the physician to change his diagnosis to typhoid fever, but eventually accomplished this object.

When I entered office in 1906, every physician with an average practice treated at least half a dozen typhoid cases every summer, and our busiest practitioners counted it a poor year when they did not have twice that many cases. In recent years we have had only about one case to every three or four physicians, and scarcely this number in private practice. One result of this, I fear, is going to be that the average physician will not see enough typhoid fever to become reasonably skilful in its handling, and this may result in an increased case fatality. This can be obviated only by hospitalization of all typhoid cases, a course which has many other things to commend it.

E. C. LEVY, M.D., Richmond, Va.

Director of Public Welfare.

"HITHERTO UNDESCRIBED SIGN IN DIAGNOSIS OF LETHARGIC ENCEPHALITIS"

To the Editor:—I was much interested in the description by Dr. Thomas F. Reilly (*THE JOURNAL*, March 13, 1920, p. 735) of a hitherto undescribed sign in lethargic encephalitis. This sign (the abnormal involuntary twitching of muscle bundles) was apparently not present in last year's epidemic, but has been noted with regular frequency in the cases coming under observation this year. There are apparently three types of influenzal invasion of the central nervous system which have, as a distinguishing feature in common, these myoclonic movements: One type is associated with a diffuse neuralgic syndrome, toxic delirium and a fatal termination. Another type presents only myoclonic movements and a neu-

ralgic syndrome which proceeds to an early recovery. The third type presents the foregoing symptoms, which after a variable time become merged into a pure syndrome of lethargic encephalitis. There is no doubt that all these phenomena are simply the expression of the same infectious agent.

Dr. Reilly considers the term "lethargic" unfortunate, as the condition of the patient belies the designation. In this connection I would consider the term "encephalitis" equally misleading. I refer particularly to those cases which present only diffuse myoclonic movements and neuralgic symptoms. As stated before, this type of case reveals no evidence of "encephalitis" on close scrutiny. Lethargic encephalitis is becoming a sort of junk-heap on which every infection with neural manifestations is being dumped. In the interest of scientific and clinical accuracy, a revision of the nomenclature would indeed be welcome.

CHARLES ROSENHECK, M.D., New York.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SYRUP OF THYME

To the Editor:—A short time ago I received a sample of "Pertussin" and used some in an obstinate case of bronchitis with excellent results. I have since received a catalog from a pharmaceutical firm, which advertises syrup of thyme. I have searched for a formula to make my own syrup of thyme, but have not been able to find one. Will you publish one?

E. F. BENNER, M.D., Saffordville, Pa.

ANSWER.—The subjoined formula yields a product very similar to "Pertussin" in taste, flavor, composition, and probably in activity as well:

Fluidextract of thyme	15 c.c.
Glycerin	15 c.c.
Syrup	to make 100 c.c.

The original German preparation contained 1.5 gm. of sodium bromid in each hundred cubic centimeters, and this might be added to the foregoing formula with advantage, so far as action is concerned. However, a sample of "Pertussin" purchased in the open market in the United States failed to respond to tests for bromids.

As fluidextract of thyme is not official, this formula is presented as furnishing an acceptable preparation:

Thyme, in No. 60 powder..... 100 gm.

Moisten with a mixture of:

Water	25 c.c.
Alcohol	15 c.c.
Glycerin	10 c.c.

After standing five hours, pack in a percolator. Exhaust with a menstruum of alcohol, 1 volume, and water, 3 volumes. Reserve the first 85 c.c. of percolate. Concentrate the weak percolate to a soft extract and dissolve in the reserved portion. Make up to 100 c.c. by addition of a mixture of alcohol, 1 volume, and water, 3 volumes.

Other aromatic expectorants, such as terebene, terpin hydrate or creosote, might be expected to have similar but greater effect in chronic bronchitis.

Care of the Eyes.—To read or study when tired or drowsy is to strain the eyes to a dangerous degree. Avoid evening study whenever possible. If you are using your eyes by artificial light, be sure the light does not shine directly into the eyes, and try to have it come from behind and to the left side so as to avoid the harmful glare. Never sit with the gas or electric light directly in front of you. If electric light is used, the bulbs should be wholly or partly frosted. The best form of artificial illumination for the eyes is the so-called indirect system, where the light is reflected from the ceiling and walls of the room in a soft glow and where all glare is entirely hidden by an opaque shield.—W. M. Carhart, *Pub. Health*, Michigan, September, 1919.

WEST VIRGINIA: Charleston, April 13. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

Kansas February and June Examinations

Dr. H. A. Dykes, secretary of the Kansas State Board of Medical Registration and Examination, reports the written examination held at Topeka, Feb. 11, 1919. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Four candidates were examined, all of whom passed. Fourteen candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	No. Licensed
University of Illinois	(1919)	1
St. Louis University	(1918)	1
Meharry Medical College	(1918)	2
College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Hering Medical College, Chicago	(1909)	Oklahoma

*Diploma withheld pending completion of hospital internship.

†Graduation not verified.

Georgia October Examination

Dr. C. T. Nolan, secretary of the Georgia State Board of Medical Examiners, reports the written examination held at Atlanta, Oct. 14-15, 1919. The examination covered 10 subjects and included 100 questions. An average of 80 per cent. was required to pass. Of the 14 candidates examined, 13 passed and 1 failed. Twenty-one candidates were licensed by reciprocity. One candidate, a graduate of the University of Virginia in 1917, was licensed on presentation of a certificate from the National Board of Medical Examiners. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Birmingham Medical College	(1915)	80.9
Chicago College of Medicine and Surgery	(1917)	87.3
Loyola University	(1919)	90.3

Social Medicine and Medical Economics

COMPULSORY HEALTH INSURANCE

M. L. HARRIS, M.D.
CHICAGO

In THE JOURNAL, March 6, attention was called¹ to the economic burden which workmen's compensation acts impose on the medical profession, owing to the inertia of the profession when it comes to economic matters. Tradition seems to have blinded the medical profession to everything but its work. Workmen's compensation acts were agitated publicly some time before they were made into laws, but physicians took no action in the matter. At the present time a proposition of much greater magnitude than workmen's compensation acts and of infinitely greater importance to the profession is being quite extensively agitated throughout the country, and unless the medical profession is alert it will wake up later to find itself again suffering under a burden from which it will be difficult or impossible to extricate itself.

THOSE INTERESTED IN HEALTH INSURANCE

Compulsory health insurance is one of the most important economic problems that has ever confronted the American people; therefore, it should be carefully studied in all its aspects. Without considerable thought and study, it is impossible for one fully to comprehend the magnitude of the undertaking. There is scarcely a class of persons who would not be affected more or less directly by it. There would be the great hordes of independent, free thinking individuals, who would be compelled to accept and pay for the insurance, whether they wanted it or not; the thousands of industries that would be forced to contribute to the fund; the medical profession that would be obliged to assume the responsibility of carrying out the terms of the insurance; the innumerable officials composing the working machinery, and finally, everybody else who would be taxed for the enormous upkeep of it all. The effect that a scheme of this kind would have on each of these groups is a study by itself. It is by no means clear that it would be an advantage even to the class that it is intended to benefit.

INDIVIDUALISM

That good health and a good physique are most desirable qualities in an individual and even essential to the welfare of a nation will be admitted without argument; hence, no time need be wasted on that phase of the subject; but if the events of the last few years have taught us anything, they have taught us that individualism is likewise an essential qualification of a people's greatness. Individualism, independence, freedom of thought and action are necessary to the upbuilding of a race of people sufficiently resourceful to meet successfully all the obligations and duties of life. Every time the state relieves the individual of a responsibility in life, it weakens the individual's character, which must inevitably react detrimentally on the evolutionary development of the people. The only restrictions to individualism which should be enforced are those made necessary by community existence, and that is too elementary a subject to require consideration here.

Before discussing further the effects of compulsory laws on the development of the individual, let us review briefly the arguments of the proponents of compulsory health insurance. The statement is frequently made that compulsory health insurance is but another step in the same direction

as workmen's compensation acts, and if the latter are sound in principle and beneficial in their effects, the former, being but a step forward in the same direction, must likewise be sound in principle and beneficial in its effects. This conclusion is erroneous because of a lack of relation between the premises. The principle underlying workmen's compensation acts is definite and distinct, namely, injuries to workmen arising out of, and in the course of, their employment are a direct charge on the cost of production; but no such principle underlies compulsory health insurance. If accidental injuries to workmen were always preventable, it would be the duty of the state to enforce such rules and regulations as would effectually prevent their occurrence, instead of enacting laws to compensate the workmen in some manner for the damage done. It would not only be much cheaper to prevent the damage but infinitely more humane.

Arguing along this line, the proponents of compulsory health insurance claim that as some diseases may be directly connected with the character of the work, all diseases in workmen should be compensated for the same as accidental injuries. There are many fallacies in this line of argument. In the first place, the diseases which are directly caused by the character of the work are very few indeed, and these can be readily prevented by proper working conditions. If a disease can be prevented by having proper working conditions, it is plainly the duty of the state to see that such conditions are provided, and not tax the people to cure a disease when it would be much easier and cheaper to prevent it. If there should be a disease which was caused directly by a particular line of work in an industry, and it were not preventable, then the care of a workman thus made ill should be a direct charge on the cost of production in the same manner as an accidental injury.

INFLUENCE OF ECONOMIC CONDITIONS

Much has been written about economic conditions and the influence which they may have in causing disease. Among these may be mentioned working conditions which cause fatigue; morbidity and mortality statistics according to occupation; effects of irregular employment on health; inadequate diet; bad housing conditions and overcrowding, and unfavorable community environment. It will be admitted that these conditions and others that might be mentioned may be factors of greater or lesser degree in the causation of some diseases, but it is not shown that compulsory health insurance would modify or change any of these conditions or in any way mitigate their effects. Bad housing conditions and overcrowding, unhealthful working conditions, and unfavorable community environment are all matters which are, or should be, under the supervision of municipal and state public health departments; irregular employment and unemployment are industrial problems, and inadequate and improper diet are matters of intelligence and education. A lack of intelligence and of education, both general and moral, and a disregard by the educated, as well as the uneducated, of the ordinary common sense rules of hygiene are much greater causative factors in the production of disease than all of those previously mentioned, but it is impossible to legislate effectually against conditions such as these. Certainly compulsory health insurance would be more likely to increase than to decrease the tendency to them, by reason of the removal of restraint and responsibility.

PREVENTIVE MEDICINE, THE PROPER ACTIVITY OF THE STATE

Wages and poverty and disease are familiar terms much used in the discussion of this subject. Wages below a certain point, which, though relative, is always definable, spell poverty, and morbidity and wages are associated within certain limitations in inverse ratio. The lower the wage, the

1. Harris, M. L.: "The Physician's Burden Under Workmen's Compensation Acts," J. A. M. A. 74:694 (March 6) 1920.

higher the morbidity; as wages rise, morbidity falls, until it reaches what may be termed the "normal" rate. Other things being equal, this ratio between wages and morbidity in general terms is quite constant. The point at which the normal morbidity line crosses the wage line indicates what may be called a living wage. It is recognized that this is not a fixed point for all individuals, or for all classes of individuals; but when dealing with numbers, the principle holds good. When the wage or the income falls below the point mentioned, poverty begins, and sickness increases. With increased sickness comes a further decrease in income, and consequently greater poverty. Thus a vicious circle becomes established, from which it is often difficult to escape.

These are fundamental facts in economics. The question now arises: What should be done to help those whose income falls below the normal living wage and who thereby suffer from increased morbidity? It is plainly the duty of the state to study this problem and to solve it if possible. Shall the state by a system of compulsory medical treatment simply attempt to cure the ills of the unfortunate, or shall it, by proper preventive measures and by aiding in the adjustment of sociological and industrial conditions, enable the people to rise to or above the normal income point, so that they may, by their own resources, fulfil their responsibilities and obligations in life? Viewed from the standpoint of the ultimate good of the people, it would seem that there can be no question as to the course the state should pursue. If the state will extend the work of its health department to a legitimate extent along the line of preventive medicine and endeavor to correct insanitary working and housing conditions and educate the public in personal hygiene, there will be no occasion for compulsory health insurance. These are all legitimate functions of the state. There are certain responsibilities and obligations in life that must always rest with the individual if he would remain free; and when the state attempts to assume these, even though it may seem expedient at the time, it does so to the eventual detriment of the individual.

The statistics of the draft showing physical defects sufficient to disqualify for the army in about 30 per cent. of the young men of this country is often used as an argument in favor of compulsory health insurance. It should be remembered, however, that ours was a select army, and only the most perfect specimens of manhood were taken. It does not mean that all those rejected were unfit for the usual occupations of life. The largest single cause of rejection was defective vision, due simply to errors of refraction, a condition which may be relieved by the use of glasses but which cannot be prevented or cured. The defects were found among the rich who have always been well taken care of medically, as well as among the poor; hence it is perfectly evident that compulsory health insurance would not have prevented the defects, but some of them might have been obviated by a reasonable amount of proper physical training. The same kinds of defects were found with equal frequency in men of the countries which have been the longest under compulsory health insurance; on the other hand, no finer specimens of young manhood, both physically and mentally, ever formed an army than composed the American Expeditionary Forces. It is certain, therefore, that compulsory health insurance finds no support in the draft statistics.

LOCAL NATURE OF THE DISPENSARY PROBLEM

There are a few eminent members of our profession who believe compulsory health insurance to be desirable. These gentlemen have studied the subject from the point of view of the large city dispensary and clinic. They see a large number of poor people who visit these dispensaries daily and who, they believe, are not receiving adequate medical

treatment. They argue that if all these patients were insured they would be able to pay the dispensaries for their treatments; the dispensaries would then be able to build up larger institutions, which could pay the attending physicians for their services, and thus provide the sick with better collective medical care. Any one who is familiar with the dispensary evil and the suffering of the poor in the tenement districts of large cities will appreciate the point of view of the gentlemen who earnestly desire the betterment of the condition of these people; but isn't the dispensary question rather a local one? The same conditions certainly do not obtain throughout the country or even throughout a state. The commissions that have been appointed by several of the states to investigate the question of health insurance report that conditions vary greatly in different states and in different parts of the same state, and some of the commissions see no necessity for the adoption of compulsory health insurance. It will be admitted that the dispensary question and inadequate medical care of the poor in large cities are serious problems, and it is even possible that compulsory health insurance might bring temporary relief; but it would be at the expense of future harm. In matters of such weighty importance, isn't it a short-sighted policy that acts only for today and disregards tomorrow? Why should a measure that is ultimately detrimental in its effects be imposed on an entire country or state for the temporary relief of a condition that is local, and which should be remedied by prevention rather than cure? It should not be inferred from this that there are no poor in small communities; but the conditions are very different from those existing in large cities. Again, no measure of the magnitude and importance of compulsory health insurance, the effects of which are in any way doubtful, should be thrust on a people, for it is a well known fact that a principle once written into the law seldom becomes erased, and the baneful influence of such laws are cumulative, and eventually drag a people down.

In a subsequent article the effects of compulsory health insurance on the medical profession will be discussed.

Medicolegal

Osteopath Not a Physician

(*Ex parte Rust (Calif.)*, 183 Pac. R. 548)

The Supreme Court of California, in denying in this habeas corpus proceeding the petitioner's application for release from custody on a conviction of violating the optometry law, says that he was licensed in 1907 to practice osteopathy, and contended that he was a physician and was entitled to practice optometry by reason of the exception contained in the optometry law that its provisions should not be construed to prevent duly licensed physicians and surgeons from treating or fitting glasses to the human eye. To support his contention that the practice of osteopathy was the practice of medicine, and hence that he was a physician, the petitioner relied on the general definition of a physician as one who practices the art of healing, and on cases in which those engaged in the practice of osteopathy have been held guilty of violating laws regulating the practice of medicine. He also claimed that he was a "physician" practicing "medicine" within the meaning of the Medical Act of 1901, in force at the time his license to practice osteopathy was issued, which provided that those, among others, should be deemed as practicing medicine or surgery within the meaning of this act who, for a pecuniary or valuable consideration, "perform any operation for the relief or cure of any bodily injury or disease." The question thus raised was not free from difficulty, for the reason that neither the medical act of 1876 nor any of the succeeding acts defines a "physician" or "surgeon," or a "physician and surgeon," or expressly provides for the

license of a "physician." The optometry law of 1903, in stating the exception, is similar to that of 1913, as is the amendment of 1907, in using the term "physician and surgeon"; but the amendment thereto in 1909 uses the expression "physician or surgeon." There was therefore some basis for the claim that at the time of the issuance of the petitioner's license (March 6, 1907) these terms "physician" and "surgeon," not being defined by statute, should be construed in their broad and general acceptance. However, the same legislature which adopted the optometry law of 1913 also adopted a law regulating the practice of all systems of healing. By this law provision was made for the issuance of a certificate known as a "physician and surgeon's" certificate, and another to be known as a "drugless practitioner's" certificate, the latter certificate covering the right to practice osteopathy; and the court holds that the provision of the optometry law of 1913 mentioned above refers to those holding a "physician and surgeon's certificate," as authorized by the medical act of the same year. Moreover, the court thinks it fairly apparent that the legislature has, in effect, always used the terms "physician" or "surgeon" and "physician and surgeon" as applied to those practicing medicine and surgery within the meaning of the various medical acts, as contradistinguished from the practitioners of osteopathy. Wherefore, the court holds that the license of the petitioner, although issued before the optometry act and the medical act of 1913, did not authorize him to practice optometry under the exception in favor of physicians and surgeons. Nor did the license to practice osteopathy issued under the law of 1901 authorize the licensee to practice every known healing art which did not involve the use of drugs, or major surgery, including optometry. The present laws authorize the petitioner to practice osteopathy, and nothing more, by reason of his license issued under the law of 1901. The court cannot say that the science of osteopathy includes optometry. The discrimination between the holder of a physician and surgeon's certificate and the holder of a certificate to practice osteopathy is not unreasonable, for it is based on different training.

Paralysis of Face Following Mastoid Operation

(Finke v. Hess (Wis.), 174 N. W. R. 466)

The Supreme Court of Wisconsin, in affirming a judgment on a verdict directed for the defendant in this action for alleged malpractice, says that it was insisted by the plaintiff that the defendant, in performing a mastoid operation, severed the seventh or facial nerve. At the close of the evidence, a verdict was directed for the defendant. The question was whether there was sufficient evidence to carry the case to the jury. Paralysis of the face was shown, and there was evidence that severance of the nerves would cause such condition. But the evidence also showed that the paralysis might, from other causes, well follow an operation skilfully and properly performed. It was shown that paralysis might have been caused by a debiscence, or by bandaging after the operation, or by cold drafts, and possibly other causes. In order to warrant the court in submitting the case to the jury there must be some evidence that the defendant severed the facial nerve, and there was none in the record. On the other hand, there was positive evidence, not only by the defendant, but also by a specialist of Chicago, who opened up the old scar in an effort to relieve pressure on the nerve, that the nerve was not severed. It was contended that this specialist admitted that the nerve was severed, but the evidence did not support that contention. It was based on the testimony of a woman; but her evidence as to what the specialist said when he was not under oath was not competent, except as laying a foundation for impeachment. Moreover, she admitted on cross-examination that the specialist might have said that the nerve was injured, not severed. Some reliance was placed on the opinion of another physician, but his opinion could not raise a conflict with the positive undisputed evidence that the nerve was not severed, and that other causes existed for the paralysis. Proof of a bad result raised no presumption of negligence in this case.

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Joint Annual Conference of the Council on Medical Education of the
American Medical Association with the Association of American
Medical Colleges and the Federation of State Medical Boards
of the United States, held in Chicago, March 1-3, 1920

(Continued from page 826)

Research in the Teaching Laboratories

DR. OSCAR KLOTZ, Pittsburgh: My plea is for a closer cooperation of the various laboratories in modern medical schools. We are still working under the handicap of the tradition of the past, when the researches were undertaken by isolated individuals in apartments with closed doors. There are many problems of medical research which can be carried out equally well, without regard to the location of the institution. Certain necessary factors are essential: the personnel, the laboratory with all its accessories, and a library. But there are other problems which do not lend themselves to this ready approach. The yellow fever problem could not have been undertaken in Canada, nor industrial diseases in Washington. The present time lends itself very well to directing the energies of our laboratory system in the study of problems most nearly related to the local community life. For example, there is no better place to continue the study of shock than in our large industrial centers. The tropical and subtropical diseases logically belong to the South and the large seaport towns in close commercial contact with endemic centers. Can we not make greater headway by studying the questions which lie at our door? Jenner's opportunity was just such a one. Against advocating such a plan, and one whose disposition would best be placed in the hands of the National Research Council, may be brought the argument that we should be forgetting the emphasis to be laid on a study of the everyday fundamentals related to less localized problems. It is not intended to advocate the restricting of the activities of any one or group of individuals to concrete practical problems, but that each would also continue his investigations in the field of his personal choice. Moreover, the correlation of two such

divergent fields of investigation would tend to make the researchers broader men.

Problems for investigation and the opportunity for attacking them lie before every department of our medical schools, and there can remain only two reasons why more is not accomplished: We "cannot make brick without straw," and although our universities are realizing the value of research and are making the facilities available as quickly as funds will permit, this in not a few institutions has been a slow process. Rarely does a university appreciate the value of research to an extent to add to the departmental budgets money to be devoted for this purpose. The endowment of research fellowships within the teaching departments is to be encouraged, and sufficient money to provide the necessary equipment must be urged. Some schools of medicine have found it easier to obtain a research budget by establishing certain definite research departments whose personnel has no teaching responsibility nor a working relation to any particular department in the institution.

A word about undergraduate research in the medical sciences: From time to time a plea has been made by medical educators for the recognition of student researches, either as a part of their laboratory exercises or as a final thesis prior to graduation. Student research is distinctly different from the research performed by the graduate scholar. For the undergraduate, the carrying out or verifying of a technic previously devised, or his acting in the capacity of personal assistant to his instructor, may be perfectly adequate methods of training for research. It is inadvisable to assign true research problems to the undergraduate not only because of his inadequate training but also because of his essential studies in other departments. However, the summer months often offer an opportunity for the occasional student, and advantage is taken of this.

What is true of the fifth year in the hospitals may also apply to the laboratories of the teaching departments of medical schools. It should be possible in all states to credit work done in the fifth year under the direction of the medical school laboratories at the same rating as the hospital service. With such an arrangement it would be possible to produce a larger number of scientifically trained men for practice, and give them their first real insight into original laboratory research.

Research in Clinical Medicine

DR. G. CANBY ROBINSON, St. Louis: The establishment of clinical medicine on a university basis necessitates a revision of the usual divisions of the subject. Internal medicine, pediatrics, surgery and the specialties which have grown up about them must be brought close together, and all must be considered part of the science of clinical medicine, the study of disease in living human beings. The technic of treatment has made the division into the various groups desirable and necessary, and this division must be maintained. On the other hand, the study of all human disease affecting all organs of the body must be included in the science of clinical medicine and be pervaded by the same spirit of scientific research. No special consideration should be reserved for internal medicine which is not shared by surgery and by all the medical and surgical specialties. Obstetrics is excluded by our definition, but only so far as childbearing is to be excluded as a disease. There are many medical problems associated with it.

The department of clinical medicine should consist of a group of men which, by virtue of the special training of its individual members, can bring to bear on the problems of disease a knowledge of all the ancillary or contributing sciences. It is essential that there be men trained in chemical, physiologic, bacteriologic and biologic methods who have a knowledge of the present day conceptions of these sciences. Physical chemistry and physics are also becoming more and more necessary for the solution of clinical medical problems. This group of men must work together as a team, in order to bring research to its greatest development. That this is now being done is one of the most hopeful signs. The unit system, as the English call it, has great possibilities. The group must be presided over by a man who has gained the

headship of the department by virtue of scientific attainments and achievements, and because of demonstrated ability in the performance of the manifold duties he is called on to discharge. He should be alive to the contribution which each member of the group can make. He should not only coordinate the whole department, and himself participate in research, but he should also bring each member of the department and his work into sufficient intimacy with all the other members so that the entire group will go forward together in the study of clinical medicine.

The facilities necessary for the development of a university department of clinical medicine consist in an adequate hospital and outpatient plant under the control of the head of the department, and organized especially for carrying out the primary objects of the department, namely, research and teaching. The department must be built up about this plant and the needed laboratories and accessories must be conveniently placed and adequately equipped. It is very desirable that the hospital wards should constitute an integral part of the department. Even the most carefully planned affiliation between the university and a hospital controlled by an outside board of trustees may prove to have its disadvantages, no matter how much in accord each party in the agreement may be.

If research is recognized as an essential factor in education, then every effort should be made to foster it from this point of view alone. If clinical medicine is to be developed along the lines indicated in this paper, there can remain no arguments relating to the desirability of the so-called whole-time plan of clinical teaching. The head of the department and the principal members of the staff must devote their entire time to the demands of the hospital and laboratories and to the training, directing and teaching of the younger students. The salaries of men devoting themselves to research and teaching of clinical medicine should be adequate for their needs, and should be adjusted with consideration for the many added duties and responsibilities that arise from their care of and contact with sick and injured persons.

DISCUSSION

MR. ABRAHAM FLEXNER, New York: Nothing is too good in respect to ideals and equipment, facilities and resources for a medical school. A practical question in connection with the realization of any of these ideals or standards or criteria, is how, in a country in which educational funds are derived as they are in America, these things are to be paid for. We have told these medical schools what they ought to do and what to have in the way of equipment and facilities to remain in good standing. They have said: "That is all very well, but consider what these things cost, and who is going to pay for them?" The Council on Medical Education is the main factor in setting up criteria as to what is decent and desirable in respect to medical schools, but it has not yet, so far as I know, created a committee on finance which will help these schools in different parts of the country to find the means to do the things which the Council assures them ought to be done. The situation is different from that which exists, for instance, in Germany, where the government tells the medical school what it ought to do and what it ought to be, and then says, "Here is the money with which to do it." One of the devices that the Council on Medical Education early and properly resorted to in the efforts to secure ultimately the funds needed to finance medical schools was to take the position that a properly equipped, endowed and thorough medical school ought to be a department of a university. It does not mean that all medical schools have got immediately to be of one type. This is quite possible in Germany, where they have a sort of paternalistic government that does things, to which there is no opposition, to carry out these things on a more or less uniform basis; but in a country in which higher education is developed, as in American, that is physically impossible. We have enormous discrepancies in both private and taxable wealth; we have enormous discrepancies in public sentiment; and it is impossible for a public educational system, or a university system, to detach itself completely from these

varying local conditions. We must therefore accept the fact that for many years we are not going to have in America, in all probability, short of a miracle, of which I see no signs, standardized medical schools, but we are going to have considerable varieties. We hope to embody minimum standards in the way of preparation of students, preparation of teachers, and facilities, laboratory and clinical; but there is going to be a much greater discrepancy in this country for a long time to come than existed in Germany, where homogeneity was brought about by the leveling and elevating action of a powerful central government. I am a believer in the virtues of the full-time plan under certain conditions. It has never entered my mind that there will be in this country for a long time to come anything like a general uniform movement toward the installation of a rigid full-time plan in clinical branches. The fact of the matter is that the full-time plan covers relatively a small part of the activities of either school or hospital. It is, I think, a luxury, if we may call it so, to develop the highest possible improvement, because it promises to promote scientific development, to produce an improved teacher and investigator, and perhaps gradually to raise the entire level; but any premature movement toward the attainment of this end would in my judgment be a great mistake.

DR. FRANK BILLINGS, Chicago: Dr. Jessup did not mention some of the factors and functions of a state university when he omitted the question of prevention. I do not think he used the word prevention throughout his paper. During the last year the Illinois legislature enacted a law which enabled the state to go forward with the reconstruction and rehabilitation of the crippled. It defines those who are disabled as not only those injured but those who are disqualified because of disease, and those who were interested in the passage of that bill had no word put in it concerning prevention. One wonders, therefore, if in the function of the state through its university or officials we are going to care for the disabled without any question as to the prevention of these things, as was done so well in the army during the war.

The full-time clinical teaching policy originated twenty-two years ago in the brain of Dr. William R. Harper, who, as president of the University of Chicago, became interested in medical teaching. The founder of the University of Chicago, and the board of trustees at that time were not in favor of it; but President Harper persisted in a thing which he considered right, and hence Rush Medical College became affiliated with the University of Chicago. In this way President Harper thought he could more quickly carry out his ideas of medical teaching. He advanced the requirements for admission to that medical school rapidly. In 1902 he presented a proposition to the board of trustees, which was accepted, of making the university medical school with full-time teachers. I have been an advocate of full-time medical teaching since that time.

DR. J. WHITRIDGE WILLIAMS, Baltimore: The reason the full-time scheme became necessary was because, as Dr. Bevan has said, the men who attended to their business, giving half of their time to business, and the other half to teaching, knew perfectly well at the end of the year that they had done their duty neither to the university nor to their patients. The really provocative thing for the full-time plan was the fact that many of our best clinicians were financial hogs and prostituted their university positions for money, and expected their younger colleagues to do the work which they capitalized. We have had the full-time scheme in operation in Johns Hopkins for a number of years, and I have no hesitation in saying that, on the whole, it has been an unqualified success. Nothing is perfect, but there is no doubt about the general success of it.

DR. O. F. HENDERSON, Toronto, Ont.: If we are going to teach fifty or a hundred students adequately with only full-time men, it will mean a very large budget in the way of salaries, etc. I think it will be some time before we shall be able to carry out a full-time scheme on an extensive scale.

DR. RAY LYMAN WILBUR, Leland Stanford University, Calif.: One difficulty we have to contend with is the confu-

sion between college and university. We have comparatively few universities and comparatively few university men in the United States. The larger proportion are college men. The college teacher does not understand a medical school. The university teacher understands a medical school. There is a distinct difference in the type of men. Most of the criticism of medical schools comes from the college type of teacher. The same thing is true of members of boards of trustees in various institutions. I was much interested in what Dr. Flexner said about medical schools being taken over by universities, because I happened to have the unique position of being an individual who held a flirtation with the university, and now I have an opportunity to take care of a medical school, and while it has distinct problems of its own, it is probably the most pleasant duty I know of. There should be some definite, tangible result of the full personal service type rendered by the clinician. In carrying out the full-time plan we must remember the point Dr. Billings brought out—leadership outside the walls of the hospital from the great clinicians just as we get leadership in all other fields. If we lose track of that, we shall develop specialized branches of medicine, men that will be college men that will be interested in the medical field. The university must keep in touch with everything that is going on and supply the leaders, and in medicine we must particularly keep that in mind.

DR. E. P. LYONS, Minneapolis: With regard to the full-time proposition, in thinking the matter over in our environment, I have been influenced mostly by the Mayo Clinic, where no patient is a private patient. All classes and types of patients go there. I should like to see in our school a big university clinic to which people can come and go. I should dislike to have the university give its services to people free who can afford to pay. I should like to see that clinic developed as a service to all people—everybody who wants to go there—and that brings me to the plan outlined by Dr. Darrach, according to which the fees from patients are paid to the clinic. I think it is perfectly possible with that ideal in mind to have such a distribution that every man who is immediately taking care of an individual case will have the advantages of all the specialties, the laboratory and clinical departments, that can be of any assistance to him. The patient should not be referred from one specialist to another, receiving a separate bill from each specialist, but should have one bill for the whole work. That would be the scheme I would formulate to accomplish if I could in the University of Minnesota, and the only objection to it would come from the medical profession itself.

DR. ARTHUR DEAN BEVAN, Chicago: I am very optimistic. I think we are making wonderful progress. Mr. Pritchett told us a few years ago that we had accomplished more for education by these annual conferences than had been done by any other agency during the same period. The problem of inducting a medical school into a university is a difficult one, because medicine is more than a science. If it were simply a science it would be a simple matter to introduce it into a university and handle it without difficulty, just as the science of physics is handled; but it is an art, and it is a profession by which men make their livelihood. We cannot practice medicine as we would make matches or make shoes. We cannot practice medicine by machinery. There is an enormous personal element in medicine. We should attempt to develop our medical schools on business-like, common-sense, economical lines, and make such a combination with a great state for the interests of the people of the state as has been made in Iowa between the hospital that takes care of the people of the state and the medical school. I think that is a splendid scheme and should be copied widely wherever it is feasible.

Coordination of Effort in Medical Licensure

DR. DAVID A. STRICKLER, Denver: It should be the effort of every board to make it easily possible for a good man to obtain a license in any state and vice versa, increasingly difficult for a bad man to extend his field of labor. Each state must determine for itself the value of credentials presented; but in the matter of practice record, moral character and

those qualities which make the man and citizen, very important information may be best ascertained by his home board, the endorsement of which, under proper conditions, should mean much to the individual and to the board receiving it. My plea is for an interstate endorsement which shall represent the facts as they are ascertained on investigation or as based on personal knowledge of the executive officer, and not simply a statement of what the records show, though this should be included when of value to the board which is to determine whether a license shall or shall not be issued.

It has seemed to me that with the consistent efforts of the Council of Medical Education of the American Medical Association, combined with the Association of American Medical Colleges and other like bodies from the homeopathic and eclectic schools, a standard should be reached which may be accepted as evidence of medical knowledge without requiring an examination each time a man from choice or necessity changes his residence to a new state.

Report of Committee on Graduate Medical Education in the United States

DR. LOUIS B. WILSON, Rochester, Minn.: Owing to conditions since the war, probably 10,000 medical graduates sought opportunity for further study in 1919. This is probably three times the annual number in normal years. Probably 3,000 medical graduates are doing work in short courses in the United States during the current year. The supply of short courses in graduate schools is at present sufficient to take care of those seeking the kind of instruction offered, but probably more than as many more desire short courses of better grade. More good university schools might well offer opportunities for brief periods of study in limited fields to more adequately prepared general practitioners or practicing specialists.

Of 1,021 physicians recently requesting opportunity for graduate study for long terms, a large majority requested surgery. About one-sixth as many applied for medicine and one-tenth for otolaryngology. Only four applied for work in the fundamental medical sciences.

The average age at graduation of the 174 medical graduates in the University of Minnesota is 25.8 years, just a year less than the average age at graduation of the total number of graduates in 1916 from all medical schools which in 1912 required two or more years of collegiate work for entrance.

A questionnaire to representative men in special clinical fields shows that their average age at graduation was 24 years, though their average date of graduation was 1894. The respondents to this questionnaire advise a minimum of three years' graduate study after a year's general internship before beginning the practice of a clinical specialty. This is from one to two years less than the respondents themselves took for their own preparation. Of the respondents less than one-third as many advise foreign graduate medical study as had it during their own graduate preparation. Of the surgeons responding, half as many as had it advise special graduate work in anatomy. One-half more advise special work in pathology than had it. Of the internists, twice as many as had it advised special graduate work in biochemistry and physiology, and one-fourth less than had it advise special training in pathology. General practice preceding a specialty is advised by only 6 per cent. of the respondents. Seventy-six per cent. advise hospital residency or assistantship in the special field desired. Twenty-five per cent. advise assistantship to one specialist.

Attention is called to the urgent need of increasing the number of competent men in the fundamental medical sciences. To this end it is recommended that adequate endowments of teaching positions and fellowships be sought that full-time professorships in the fundamental medical sciences may pay the same salaries as proposed full-time professorships in surgery and internal medicine.

Interallied Medical Relations

DR. WALTER L. BIERRING, Des Moines, Iowa: The impressions gained by observation of the English plan of medical

education are, first, that the fundamental and general education of the English physician is on a higher plane than his medical colleagues in the United States applying particularly to those graduating previous to 1912; second, the emphasis given to the practical application of pathology, bacteriology and anatomy in the qualifying examinations has led to a lessened interest in special research studies in pure pathology, pure bacteriology and the other fundamental medical sciences.

Medical licensure in Great Britain is distinctive and vested entirely in the general council of medical education and registration of the United Kingdom, established when the first comprehensive British medical practice act was enacted in 1858. The general council does not conduct any examinations, but it decides which medical schools are in good standing, and by means of inspectors appointed from its membership determines whether courses of study and the examination of the faculties of the different medical schools as well as the three qualifying boards are satisfactory.

This plan has certain distinct advantages, the final licensure examination is done away with; and with such a representative body as the general council, with excellent means of supervising medical teaching and qualifying examinations, it is eminently fair to the interests of the profession, and the public is well protected.

An entirely different situation obtains in France. Medical education and the right to practice medicine are entirely under the control of the state, the one being dependent on the other, as the conferring of the degree of Doctor of Medicine from an authorized French university carries with it the privilege to practice.

Interstate Relations in Medicine

MR. FRANCIS W. SHEPARDSON, Springfield, Ill.: In considering interstate relations in licensure for medicine it was not the purpose to discuss the subject of reciprocity which, on first thought, might be associated with the topic. Even a casual examination, however, of the various application blanks for reciprocity required by the boards of medical examiners of various states suggests that there is much yet to be done in this field before ideal conditions are secured. The blanks differ materially in their form, language and requirements. It is at least worth a question whether it might not be possible through interstate cooperation to secure a greater degree of uniformity in these blanks and a much simpler type of application than that now generally used.

These are some of the matters relating to interstate relations in medicine which it seems to me might be worthy of consideration. The need of harmony and united effort on the part of licensing authorities of adjacent states of the Union is apparent. Through such harmony and united effort many of the evils which have attended medical licensure in the past, some of which still exist, might be ended forever.

DISCUSSION

DR. ARTHUR DEAN BEVAN, Chicago: As chairman of the Council on Medical Education, I had the opportunity to inspect a number of these institutions with Dr. Wilson. From inspection of these graduate schools, the kindest thing that one can say is that they are entirely inadequate to perform the functions which seem at this time to be required. It is quite clear this work should not be done by independent schools or by commercial schools. There is a legitimate and growing demand for the right sort of graduate instruction. The reason we have the class of institutions that we now have is that the universities of the country have not done their duty. The problem clearly belongs to the medical departments of our universities.

DR. GEORGE H. MEEKER, Philadelphia: The University of Pennsylvania has been considering this subject for a number of years, and in 1916, as a result of this movement, the Medico-Chirurgical College of Philadelphia ceased to exist as an undergraduate institution. In 1918 the former Philadelphia Polyclinic and College for Graduates in Medicine similarly joined the movement, but the war prevented any real progress from being made. At present we are giving

what we believe to be meritorious courses in internal medicine, neurology, ophthalmology, and otolaryngology, each of four months' duration, and of intensive work leading to degrees or certificates. The aim of the university is to supply the tremendous demand, although there will have been 100 such men handled during the present university session. Under the plan which the committee has been preparing for the University of Pennsylvania, it will involve a deficit of \$200,000 per annum. The income from students is estimated at a maximum of \$10,000 per annum, which is hardly a paying proposition financially. The University of Pennsylvania has about two and a half million dollars already invested in this work, and has expended in preparation for it about \$150,000 in equipment for teaching up to the present time, which by no means represents an idea of the final expenditure.

DR. HORACE D. ARNOLD, Boston: One point has not been sufficiently emphasized: Before the war a large number of our enterprising and best medical men were going to Germany and Austria for improvement in their medical knowledge and experience in various lines. Now that whole current has been disjointed by the war. Those men do not want to go to Germany and Austria at the present time, and yet that current is still in existence, and a number of men that have become interested in the improvement of their medical knowledge through the war experience are seeing and using better methods of dealing with the sick. They recognize their deficiencies, and where are those men going? It seems to me that it is up to the profession of the country, and particularly to the medical schools and universities of this country, to organize to meet this demand and to do it quickly.

DR. H. W. BRIGG, Wilmington, Del.: Dr. Strickler says it would be well to have a survey of the methods employed by the different state boards in licensing candidates after examination. This is an excellent suggestion because it would enable us to compare notes. That is the way progress has been made by the Council on Medical Education. If such a survey is to be made and brought to one of these meetings, we can derive benefit from it by analysis and comparison. His second recommendation is that we proceed with propaganda on legitimately advertising the better things of the medical profession; in other words, a propaganda of publicity.

DR. GEORGE M. KOBER, Washington, D. C.: It has occurred to me that new channels might be opened for graduate instruction in connection with the Public Health Service. This service is now preparing a large number of hospitals in different medical and industrial centers which need unquestionably to be properly supplied with an able consulting staff, and it is really the policy of that service to call to its aid the various medical and special surgical authorities as a consulting staff for these hospitals. In addition to the work in the hands of the Public Health Service, there is also a great work being done by the government of the United States in the operation of the workmen's compensation acts, which means the proper and adequate care for the sick and for the relief and recovery of men who have incurred accidents or diseases in the line of their duty when employed by the United States government.

DR. JOHN M. DODSON, Chicago: The proper line of action is to make use of our proper resources for graduate instruction for these various groups. The most interesting experiment along this line which has ever been instituted in this country is in connection with the Mayo Clinic and the University of Minnesota. It is unfortunate that we do not have more clinics of the sort that can supply their own funds and then give to the universities ample promise of support, in Boston, Philadelphia, New York, etc. I think it should be the existing medical schools, strongly established, seeking to utilize the larger resources of the hospitals in those cities. Many of the outlying hospitals in smaller cities are available for this purpose. I should like to see a continuation of the work in these numerous hospitals, now very well organized under the auspices of or with the advice and help of existing university medical schools.

- *Studies on Cerebrospinal Fluid. F. C. Becht, Chicago.—p. 1.
*Id. F. C. Becht and P. M. Matill, Chicago.—p. 126.

Studies on Cerebrospinal Fluid.—Becht reports his results of a critical study of the methods employed in the observations on the cerebrospinal fluid, detailing the status of the formation and movements of cerebrospinal fluid; the mechanical factors influencing the cerebrospinal fluid; the normal rate of the formation of the cerebrospinal fluid and its absorption, and the effect of drugs on arterial, venous and fluid pressures.

Becht and Matill report the results of experiments undertaken to determine what effect the injection of tissue extracts has on the cerebrospinal fluid and, particularly, whether or not they possess a specific stimulating action, producing an actual increase in the amount of fluid produced. They found that nearly all tissue extracts have a depressor effect on the vascular system; extracts of suprarenal and of the posterior lobe of the hypophysis have a pressor effect.

Sensory Changes in Injuries of Musculospiral Nerve. A. S. Hamilton, Minneapolis.—p. 277.

Morbi Neurales: Key Principle to Differentiation of Major Groups.—A scheme of classification of nervous diseases is offered by Southard and Solomon. Five main groups are subdivided, and each subdivision is further divided. The main groups are: (1) infections; (2) histiorrhexes, focal destruction (noninfectious); (3) neuronatrophies, sclerosis ("classical degenerations"); (4) imbalance exogenous (neurogenous); (5) miscellaneous, the algias, migraine, vertigo, tics, spasms, hydrocephalus, etc.

Case of Myxedematous Psychosis.—Uyematsu presents a case of typical myxedematous psychosis which showed, together with known symptoms, marked disturbance of coordination, vertigo and somnolence. The thyroid gland was found extremely atrophic with the gland tissue replaced by connective tissue fibers and with no isthmus. The remaining gland tissue was infiltrated by lymphatic cells. The author suspects some etiologic relationship between the congenital factor and this disease. The pituitary body was smaller than

normal, though microscopically there was no evidence of atrophy. The right ovary was removed ten years ago, the left remained atrophic, showing an evidence of chronic inflammatory process. Uyematsu suspects, having seen a similar condition of ovaries in a former case of the Danvers (Mass.) State Hospital series, some etiologic factors in certain diseased conditions of the ovaries. The pathologic changes in the brain and the cerebellum consist of arteriosclerotic alterations, general senile changes and cell changes associated with the edematous condition. The author attributes the arteriosclerotic alterations and the general senile changes to the effect of the myxedematous disease. The cell change associated with the edematous condition is considered as pathognomonic. Uyematsu believes also that there is a possible correlation between the marked atrophy of the cerebellum and the clinical symptoms of disturbed coordination and of vertigo.

Nasal Route of Infection in Poliomyelitis.—The experiments described by Flexner and Amoss relate to the conditions underlying the states of susceptibility and refractoriness to infection with the virus of poliomyelitis applied to the nasal mucosa. The authors found that an effective nasal mucous membrane prevents the passage of the energetically applied virus to the brain and spinal cord. The protective power possessed by the nasal mucosa is not in itself adequate to prevent infection with the virus placed on it, since slight injury to such independent structures as the meningeal-choroid complex favors the passage of the virus from the nose to the central nervous organs. The normal nasal mucosa is, therefore, an invaluable defense against infection with the virus of poliomyelitis; and the number of healthy and chronic carriers of the virus is probably determined and kept down through the protective activities of this membrane. Antiseptic chemicals applied to the nasal mucosa on which the virus has been deposited exhibit no great protective action and are of doubtful value. Indeed, it is not impossible that to the extent to which they may affect unfavorably the destructive properties of the nasal mucosa, they may be even objectionable. Infection with the virus of poliomyelitis applied to the nasal mucosa under conditions favorable to the extension to the central nervous organs and multiplication there may be blocked or prevented by the injection of poliomyelitic immune serum into the blood. While the exact manner and site of attack of the immune serum on the virus is somewhat conjectural, when all the available data are considered, it seems probable to Flexner and Amoss that the meeting place of the virus and immune serum is in the sub-arachnoid space.

Immunologic Studies on Yellow Fever.—It is stated by Noguchi that monovalent immune serums prepared by several successive injections in an animal naturally refractory to *Leptospira icteroides* possess the power to agglutinate in

vitro not only the homologous strains, but also all other strains of *icteroides* tested. On the other hand, a slight effect, or none at all, has been observed when these immune serums have been mixed in vitro with various strains of *Leptospira icterohaemorrhagiae*. A similar relation exists between the monovalent anti-icterohemorrhagic serums and the various strains of *Leptospira icteroides*; that is, there is a slight agglutinating effect in some instances on the *icteroides* strains, but it is never so strong as that occurring in tests against the *icterohemorrhagic* strains. The Pfeiffer reaction gave a sharper differentiation between the two groups, for in most instances the phenomenon was specific for the group. There were occasional doubtful reactions, but not enough to warrant a confusion of the two groups: Noguchi is of the opinion that there is not much doubt that an *icteroides* attack brings about, in some instances at least, a certain degree of resistance to the *icterohemorrhagic* infection. Hence, the study of the phenomena of active immunity strongly indicates that *L. icteroides* is closely related immunologically to *L. icterohaemorrhagiae*.

Serum Therapy in Yellow Fever.—The use of a polyvalent immune serum of high potency in the treatment of an experimental infection of guinea-pigs with *Leptospira icteroides* Noguchi found to be of definite advantage in checking the progress of the infection. When administered during the period of incubation, the serum was found capable of completely preventing the development of the disease, although on subsequent examination hemorrhagic lesions of greater or less number and extent were found in the lungs of the guinea-pigs which survived. Moreover, the serum modified the course of the disease, and when used in the early stages of infection prevented a fatal outcome. Employed at a later stage, however, when jaundice and nephritis had been present for several days and the animal was near collapse, the serum had no perceptible beneficial effect.

Lipovaccines.—Pneumococcus lipovaccine, according to Lewis and Dodge, confers a definite protection against pneumococcus infection in mice. The protective quality is not destroyed, and apparently is not greatly diminished, by heating to 130 C. for three hours or 120 C. for twelve hours. Typhoid lipovaccine gives rise to the formation of agglutinins in rabbits but to a lesser degree than saline suspensions. The antigenic qualities of the typhoid lipovaccine are greatly injured by heating to 130 C. for three hours.

Influence of Blood Platelets on Coagulation of Blood.—The fact that the average coagulation time of the blood (about twenty-three minutes) of pig embryos represents a coagulation time six to eight times greater than that obtained for the adult, suggested to Emmel and his associates that the number of blood platelets might be responsible. They found that numerically the blood platelets varied from 415,000 to 800,000 per cubic millimeter, a content not differing in any significant degree from that of the adult. The addition of platelet material obtained from adult pig blood reduced the coagulation time for embryonic blood to an average of 8.4 minutes, a decrease of 75 per cent. The addition of 2 drops of 0.5 per cent. calcium chlorid solution reduced the coagulation time for embryonic blood to an average of 10.3 minutes, a reduction of more than 50 per cent. The addition of tissue extract to embryonic blood reduced the coagulation time to an average of 3.7 minutes, a time essentially equivalent to that obtained for adult blood. The clot was of a much firmer character than that obtained either in the normal coagulation or in the calcium experiments. Chemical analysis demonstrated a calcium content in embryonic blood in excess of that of the adult, in the proportion of 7:5. On the whole, the results of this study suggest that the normal coagulation of embryonic blood, as far as bile is concerned, involves a process comparable with that obtained after the addition of tissue extract or kephalin, but on a small scale. In the embryonic blood in vitro, through the gradual disintegration of cellular elements, a certain amount of tissue substance (kephalin [?]) is slowly set free in the plasma, neutralizing the bile and ultimately liberating a sufficient amount of calcium to bring about coagulation.

Hemic Basophil.—Graham suggests that the basophil is a degenerated or degenerating cell. It is probably derived from the eosinophilic cells and, perhaps, in rare cases from those of neutrophilic type.

- *Simplified Method for Detection and Estimation of Distribution of Morphin. A. Morgulis and V. E. Levine, Omaha.—p. 321.

Bacteriology and Pathology of Lethargic Encephalitis.—Cultures made by Morse and Crump from fluid aspirated from the lateral ventricles of the brain in six cases resulted in securing uniformly pure cultures of a nonmotile coccus, small in young cultures, as large as a staphylococcus in old cultures, with a tendency to grow in diplococcus and tetrad forms and to bunch in small clusters. It divides similarly to a staphylococcus in three planes, stains readily with the aniline dyes, and is gram-positive. The pathologic findings seem to indicate that "encephalitis lethargica" is not a true encephalitis in the sense that general paresis or the cerebral form of poliomyelitis are examples of encephalitis, because ganglion and pyramidal cell destruction does not characterize lethargic cases. But it is a typical example of low grade "meningomyelitis," the characteristic lesions being in the meninges and white matter of the basal ganglia, pons and upper cord. Marie, in 1890, described cases similar to "encephalitis lethargica" and called them "acute multiple sclerosis." From a pathologic, as well as clinical, point of view, Morse and Crump feel that this term has much to justify its use.

Effect of Egg White Injection.—Repeated subcutaneous injections of egg white in guinea-pigs produce a constant fever, associated with most of the signs of infection, whereas the same procedure in dogs does not affect the temperature curve and does not produce fever. Cohen is unable to explain the difference of the reactions.

Leukocytes in Anaphylaxis of Serum Sickness.—In a case of serum sickness with a delayed anaphylactic reaction recorded by Barach, the blood showed at the time of the anaphylactic reaction, a primary polynuclear leukocytosis followed by the appearance of myelocytes after the organism had appropriated the available leukocytes of the circulating blood, and at the same time an increased number of blood platelets. A leukopenia followed; at which time the polymorphonuclear counts were low and the mononuclears relatively high. The eosinophilia, which has been said to accompany anaphylactic reactions in general, was absent throughout. Therefore, Barach concludes that eosinophilia is not the criterion of an anaphylactic reaction.

Metabolic Changes in Experimental Tetany.—In parathyroidectomized dogs, showing typical tetanic symptoms, an acidosis condition was always observed by Togawa, and the antitryptic power and the nonprotein nitrogen content of the blood serum were usually increased. In thyroidectomized dogs, showing no tetanic symptoms, however, an acidosis condition was never observed. On the contrary, a slight alkalosis condition was sometimes induced. The antitryptic power and the nonprotein nitrogen content of the blood serum remained almost unchanged.

Bacillus Bronchisepticus as Cause of Infectious Respiratory Disease.—Bacillus bronchisepticus was isolated by Hoskins and Stout from the nostrils, nasal sinuses, trachea, lungs and heart blood of white rats affected with a serious disease of a distemper-like character. The organism was recovered in pure culture in about one half the cases. Other organisms were found in the nostrils and nasal sinuses, and

once in the trachea. Agglutination tests pointed to the identity of the rat organism and *B. bronchisepticus* from a canine source. The serum of rats affected with the disease agglutinated both homologous as well as heterologous strains of *B. bronchisepticus* in comparatively high dilutions. One rat serum showed strong agglutination at a dilution of 1:1,024.

Simplified Method for Detection and Estimation of Distribution of Morphin.—The presence of morphin in food, or in tissues and body fluids has been determined by Morgulis and Levine by heating with 2 per cent. tartaric acid (if solid, the material should first be ground or finely minced) to convert all morphin into the soluble tartrate. The mixture is rapidly cooled, preferably on ice, to solidify the fatty material. The solid residue is removed by straining through cheese cloth, and is washed until the washings are no longer acid to litmus. The liquid, after being filtered through paper, is evaporated to a pasty consistency. The tartrate is then decomposed by the addition of an excess of solid bicarbonate which sets the alkaloid free. The evaporation is then continued to complete dryness, and the mass is powdered and extracted with chloroform to remove the free morphin. The volume of the chloroform extract is noted, and the smallest quantity of the extract is found which on evaporation (in a porcelain crucible over the water bath) leaves a residue which yields a definite morphin test. In this way the relative amount of morphin in several extracts can be determined. Besides knowing the limit of sensitivity of the reaction an approximate estimate of the amount of morphin in the original sample is possible. Inasmuch as the authors found that morphin, whether given subcutaneously or by mouth, is widely distributed throughout the animal body, finding its way into almost every tissue, they state that it is not advisable to limit the toxicologic examination for morphin to the alimentary tract alone, an examination of at least the kidney and urine and liver being indispensable.

Significance of Heart Murmurs.—This paper was abstracted in THE JOURNAL, Nov. 22, 1919, p. 1634.

Early Recognition of Diseases of Heart.—McCrae says that there are no set rules which we can apply to the early

recognition of cardiac disease in every case. The determination to observe carefully and investigate thoroughly will lessen mistakes. It is wiser to start with the idea that there is some disturbance present and prove the contrary than to make light of symptoms and fail to recognize changes which might be aided by early treatment.

*Method of Treating Dhoobie Itch. C. J. Glasson.—p. 219.

Appendectomy by a New Route.—The operation described by Whitelocke removes the appendix through the right iliac fossa in cases in which no general exploration of the abdominal cavity is called for—that is, in acute cases rather than chronic cases. The incision is made one-half inch or less internal or medial to and parallel with the anterior superior spine of the ilium, or as near to it as practicable. The cut is carried above and below this point to an equal extent and parallel with the iliac crest and spine and the attached Poupart's ligament. The length of the incision usually need not be greater than 2½ inches. The cut at once divides the skin, subcutaneous fascia, and aponeurosis of the external oblique muscle to its full length. At this stage a white line of varying distinctness may usually (roughly in about 58 per cent. of cases noted) be seen passing across the muscle almost horizontally, in a direction from the anterior superior spine of the ilium to the middle line of the body; this line which is bloodless, indicates a natural division of the muscle into an upper and lower section. With this line as a guide

the thick fibers of the muscle are incised and separated. The subjacent transversalis muscle is then similarly treated. In uncomplicated cases, and whenever there is no evidence of suppuration, as may usually be determined by palpation of the peritoneum through the transversalis fascia, this fascia and the peritoneum are divided in a direction parallel with the skin incision, medial or internal to the reflection of the parietal peritoneum on to the iliac fossa, deep to and parallel with Poupart's ligament. Where, however, an abscess is present or suspected it is safer to turn the peritoneum inward or medialward from its seat of reflection behind Poupart's ligament and to open it posteriorly from the iliac fossa. The transversalis fascia and peritoneum may be cut transversely as with the deep muscles, if the incision is likely to require enlargement. When the abdomen is opened the viscus first seen is generally (86 per cent. of cases noted) large intestine, either the first part of the ascending colon or, less frequently, the cecum. The cecum with its appendix is delivered through the wound. The appendix is removed in the usual manner and the wound is closed in layers.

Results of Protective Inoculation Against Influenza.—The results recorded by Leishman confirm and even strengthen his original anticipations, that at least a moderate degree of protection against infection might be expected, while more decidedly beneficial effects might be hoped for in a diminution of both the frequency and the gravity of the pulmonary complications.

Method of Treating Dhobie Itch.—Glasson claims to have treated many persons with Dhobie itch with success by a combination of roentgen rays and chrysophanic acid ointment (30 grains to 1 ounce of wool fat).

Eusol and its Intravenous Uses. A. L. Gregg.—p. 68.
*Influence of Salts and Other Substances on Agglutination. V. M. Syngé.—p. 76.

Influence of Salts and Other Substances on Agglutination.—The substances experimented with by Syngé were glucose (0.6 per cent. solution, and 6 per cent. solution); glycololl (0.6 per cent. solution); alanine (0.6 per cent. solution) asparagin (0.6 per cent. solution and 6 per cent. solution). The conclusions drawn from his results are: 1. The presence of any substance in solution is not sufficient to cause agglutination. 2. Asparagin has a marked influence on agglutination. 3. Other amino-acids, e. g., alanine and glycololl have no influence on agglutination. 4. Glucose has no influence on agglutination.

Influenza. B. Singh.—p. 15.

Cinchonidin in Malaria.—Twenty-four patients were injected deep in the deltoid with cinchonin bihydrochlorid. The first dose for adults was 7 minims and subsequent ones 10 minims or about 3 and 5 grains, respectively. From two to four injections were given on successive days where possible, or about 8 to 18 grains. All the cases were genuine malaria. No local or constitutional disturbance of any kind took place, except that a man who was given six injections had rather a painful arm, and another was cinchonized the very evening he was first injected; but both symptoms passed

away quickly. Quinin and arsenic were given in two obstinate cases as after-treatment. There were two relapses, showing 91.7 per cent. recoveries out of twenty-four cases.

*Intravenous Administration of Mercuric Iodid in Treatment of Syphilis. R. L. Spittel.—p. 378.

Blood Vessels and Pressure.—Not increased capillary pressure and filtration are in Hill's opinion the cause of edema, but stagnation of flow with consequent oxygen want and increased imbibition.

Complement Fixation Experiments in Influenza.—An antigen prepared by Fry and Lundie from an organism isolated in the third wave of an epidemic showed fixation of complement with serums derived from cases of influenza, both recent and those occurring in previous waves of the epidemic. This complement fixation is absent in the case of serums from normal individuals who have never had influenza. It is absent in the case of serums from individuals who are suffering from other specific diseases and are free from any recent history of influenza. An antigen prepared from another organism showed no fixation of complement with serums from cases of influenza.

Efficient and Economical Pylon.—The important features of this pylon are: (1) a bucket molded to fit the stump, and supported by a fiber cone with a satisfactory rim at the top; (2) simplicity of design; (3) light weight and low cost of production.

Intravenous Administration of Mercuric Iodid in Treatment of Syphilis.—An experience of over 4,000 of these injections, during a period of four years, convinces Spittel that this procedure is a valuable adjunct to the treatment of syphilis with arsphenamin; the combination establishing a cure (as gaged by Wassermann tests, provocative and otherwise, at varying intervals) more quickly and permanently than by any other method. The solution has the following composition: mercuric iodid, 50 grains; sodium (or potassium) iodid, 8 drams; phenolphthalein (0.5 per cent. solution), 20 minims; sodium hydrate (25 per cent. solution), about 2 drams; distilled water, to 40 ounces. The dose for an adult is from 8 to 12 c.c. given intravenously. The injection is tolerated well. The results are not only far quicker than those obtained with mercury and iodids given by any

other methods, but often even a single injection produces an effect almost as phenomenal as arsphenamin. In nerve syphilis, especially, some of the finest results are obtained. The number of injections and the interval between them vary with the particular case. An ordinary case of secondary syphilis may be treated with five or six injections each of arsphenamin and mercuric iodid, given at intervals of from seven to ten days alternately, in varying sequence or in successive courses. Often after such a series a negative Wassermann reaction is permanently obtained; if not, further courses are given to meet particular needs.

Phantom Limbs of Amputés.—More than 500 cases were investigated by Corner. His enquiries established these facts: 1. Phantoms made their appearance immediately after operation. 2. They were very unusual in the young, but were more frequent among the older patients. They were of much greater frequency and severity in military than in civil practice. 3. As a rule, they obtruded themselves less in frequency and sensation as time went on, and within eight months or a year the patient slept well, did not dream, and was only conscious of the phantom limb when he thought of it. It was a sign of considerable clinical importance if the patient was undisturbed by his missing limb in sleep and unaffected in dreams. The presence of or variations in the phantoms are often of considerable clinical value, particularly in conjunction with other physical signs, in distinguishing whether the symptoms in a particular patient are physical or psychic, bodily or mental, peripheral or central.

Estimation of Sugar in Blood in Diagnosis and Treatment.—A study of more than 700 cases of diabetes by Cammidge has shown that there is no constant blood sugar level for the appearance of sugar in the urine in quantities recognizable by ordinary tests; also, that there is no definite relationship between the percentage of sugar in the blood and either the percentage or total amount of sugar excreted by the kidneys. Patients with a permanently high blood sugar may pass comparatively little sugar in their urine, while, in some instances, a normal, or even a subnormal, blood sugar curve may be associated with frank glycosuria. In either condition, examination of the urine alone does not give a correct picture of the case, and, if it is not checked by blood sugar estimations under controlled conditions, may readily lead to mistakes in diagnosis and treatment. As a rule, young diabetics have a lower threshold point for clinical glycosuria than those of middle age, and the threshold rises with advancing years. It is, therefore, important that the presence of even small amounts of sugar in the urine of persons of middle age should not be dismissed as of little significance, unless a series of blood tests have shown that their tolerance for carbohydrates is not seriously defective. Hyperglycemia may exist without clinical glycosuria, that is with an insufficient percentage of sugar in the urine to give the ordinary tests for sugar. The reverse condition, glycosuria with a normal or subnormal percentage of sugar in the blood, is not as uncommon as is generally supposed. Cammidge's observations suggest that many cases of latent diabetes are essentially hepatic in origin, and that so long as the patient avoids sugar and foods containing sugar as such, he may take any starchy food in moderation without harm, provided that the protein and fat content of the diet are also controlled. He warns that too hasty a diagnosis of diabetes should not be made from the presence of an excess of sugar in the blood nor even from an abnormal blood sugar curve after a test

meal of sugar, for other diseases may be associated with hyperglycemia. In the later stages of nephritis, for example, the percentage of sugar in the blood is usually high, often equalling the amount met with in severe diabetes when uremia is imminent, but the blood picture is one of complete metabolic failure, and the end products of nitrogen metabolism are correspondingly increased. Some excess of sugar in the blood is usually found in patients suffering from cardiovascular diseases with high blood-pressure, even when there is little or no indication of renal disturbance. Carcinoma is another condition in which it is said that there is often moderate hyperglycemia.

Pernicious Anemia at an Advanced Age.—Ward's patient was 85 years of age. Her family history was wholly negative, and she had always enjoyed good health until she reached the age of 82, when she first noticed a progressively increasing weakness, nausea and flatulence. When Ward first saw her, which was six months before her death, she presented characteristic symptoms which permitted a very confident diagnosis of pernicious anemia before the blood was examined. She also had certain gastro-intestinal symptoms with glossitis, and numbness of the extremities. The patient's chief complaints were of sore tongue and pain in the abdomen. Ward states that chronic or acute glossitis with anemia is practically always pernicious anemia.

Relapse in Cerebrospinal Fever.—Randall reports a case in a man, aged 33, in which a true relapse occurred, ten weeks after recovery from the original attack.

The Venous Pulse.—Janowski discusses the rational interpretation and nomenclature of the elements of the normal venous pulse tracing, according to the prevailing ideas as to their origin.

Dissociation of Pulse Findings.—The oscillogram and the auscultation findings did not parallel each other in the case reported by Gallavardin and Tixier in which aortic stenosis and aortic insufficiency were accompanied with pulsus tardus and anacrotism.

Archives de Médecine des Enfants, Paris

February, 1920, 23, No. 2

- *The Arterial Circulation in Infants. E. Lesné and L. Binet.—p. 69.
- *Inherited Syphilis and Dystrophies. V. Ilutinel and H. Stévenin.—p. 77. Cont'n.
- Senile Skin in Children. Variot and Cailliau.—p. 106.
- Management of Acute Appendicitis. J. Comby.—p. 112.

Arterial Circulation in Infants.—Lesné and Binet found that the differential pressure increases with the infant's age, as also the arterial pressure in general. Feeding and crying raise the maximal pressure but sleep reduces it, as also gastro-intestinal derangement. The arterial circulation did not seem to be modified with mild infections and pleurisy. After feeding, the pulse dropped from 120 to 96. The pulse varied widely, but was over 100 in infants less than 4 months old; all after this age averaged 95. Testing the excitability of the vagus by the oculocardiac reflex induced more vigorous responses than in adults. Even in infants only 2 weeks old, the heart beat dropped from 120 or 130 to 90 when the pressure was applied to both eyeballs, but it ran up again at once. Inhalation of amyl nitrite caused pronounced vasodilation in infants 3 months old but not in infants less than a month old. This test is not borne well by infants.

Inherited Syphilis and Dystrophies.—In this second installment, Hutinel and Stévenin discuss the direct, partial, and the indirect, generalized, dystrophies for which syphilis is responsible, and also the hereditary dystrophies, with examples of each. In some of the children the head is large, the veins in the scalp and chest are prominent, and there is occasional headache or there are signs of colitis, or the hands and feet show a tendency to cyanosis—all with positive Wassermann reaction. Under specific treatment the children began to thrive at once. The writers comment on the sclerosis and sensitization, and on the arousing of lesions from inherited syphilis by some accidental infection or intoxication, especially during epidemics of scarlet fever, diphtheria or typhoid. Grave symptoms are often noted from the liver, brain, pancreas or suprarenals which would be ascribed to the acute infectious disease if the positive Wassermann reaction did not suggest that syphilis had provided a point of lesser resistance. They have seen typhoid fever induce the flaring up of an old syphilis that had long been apparently extinct, and lead to a fatal termination. On the other hand, the syphilis may imprint an especially severe character on an acute disease, enhance its severity, prolong it and entail complications. When tuberculosis develops in a syphilitic, or the tuberculous acquire syphilis, the tuberculous lesions often tend to sclerosis, and may be favorably influenced by specific treatment and hygiene. Or the tuberculosis may pass into a torpid stage, with amyloid degeneration, the tuberculous lesions affecting preferentially the organs already impaired by the inherited syphilis.

- *Lethargic Encephalitis. F. Vidal.—p. 81.
- *Hypernephroma in the Uterus. H. Hartmann.—p. 90.
- *Electric Treatment of Tuberculous Osteitis. E. Doumer.—p. 93.
- Undernutrition as Factor in Deficiency Disease Phenomena in Pigeons. A. Lumière.—p. 96.

Lethargic Encephalitis.—Widal observés that the virus causing this disease seems to affect scattered small patches of the nervous system, skipping the intervening areas. This imprints a peculiar physiognomy on the malady. In one case, typical ankle-clonus and the toe phenomenon were the only signs beyond the fever, somnolency and ptosis, with none of the other disturbances which usually accompany ankle-clonus.

Hypernephroma in the Uterus.—Hartmann does not know of any case on record like the one he reports in which a large tumor, evidently of aberrant suprarenal tissue, had developed in the uterus. The term corticosuprarenaloma seems preferable, he says, as tumors of this kind develop exclusively from aberrant suprarenal cortex cells. He knows of ten or twelve cases of such aberrant suprarenal cell tumors in the broad ligament and ovary. In the uterus case related, there were several local recurrences, but the suprarenals proper have shown no signs of disease during the three years to date.

Electric Treatment of Tuberculous Osteitis.—Doumer now announces that the cases he published eight years ago as cured by application of the high frequency current have had no recurrence since. The permanent efficacy of this treatment for tuberculous osteitis is thus established. In four of his later series of twenty cases the lesion was in the foot and of long standing. In the only two cases in which the treatment failed, the lesion was on the hand, and there was one recurrence in another case requiring repetition of the treatment. The sitting was for ten minutes daily or three times a week, the current 80,000 volts interrupted up to 800,000 or 1,000,000 times a second.

Bulletin Médical, Paris

Jan. 31, 1920, 34, No. 6

- *Acute Purulent Pleurisy. C. Villandre.—p. 87.
- *Chronic Empyema. A. Cauchoix.—p. 91.
- Suppuration in Traumatic Hemothorax. P. Ameuille.—p. 94.
- Roentgen Ray Findings with Purulent Pleurisy. P. Cottenot.—p. 98.

Acute Purulent Pleurisy.—Villandre opens this pleurisy number of the *Bulletin* by describing the preferable technic for pleurotomy as the proper treatment for purulent pleurisy.

The condition of the lung and the general condition must be such as not to contraindicate the intervention, knowing the exact site of the abscess and draining at the lowest point. Another indispensable precaution is the determination of the micro-organisms involved: The tubercle bacillus contraindicates pleurotomy, while the streptococcus, associations of germs, and putrid pleurisy demand immediate pleurotomy. Pure pneumococcus pleurisy does not always require pleurotomy, he adds. Local anesthesia is all that is needed, except for restless young children. Rib resection must accompany the pleurotomy to allow removal of the false membranes with pneumococcus or streptococcus pleurisy. Provision for drainage should be ample, but managed so as not to promote the collapse of the lung. Antiseptic lavage or intermittent flushing of the cavity is necessary with the streptococcus or associated microbes or the germs of putrid or gangrenous pleurisy. As soon as the temperature is normal, breathing exercises should be begun and kept up and the spirometer used to combat the tendency of the lung to retract.

Chronic Empyema.—Cauchoix discusses the reasons why empyema has so often resisted all treatment. Defective drainage or a persisting foreign body is usually to blame, a scrap of drain or of gauze or a chip from an instrument or piece of suture material—all of these have been found in empyemas. Osteitis of a rib close to the fistula may be a factor, and raying may reveal a second pus pocket. An instructive case is related by Picquet in which an empyema that had lasted for six years healed up at once when a secondary pus pocket in the lumbar region was incised and a long drain passed through this incision and up through the diaphragm into the pleura. The various methods for repair when suppuration has been arrested are compared. The prognosis is much better since Carrel-Dakin irrigation or insufflation of oxygen has been applied to these old cases.

Bulletins de la Société Médicale des Hôpitaux, Paris

- Tardy Sequelae of Chest Wounds. E. Sergent and P. Pruvost.—p. 1029.
- Remote Results of Chest Wounds. Tuffier.—p. 1047.

The Arterial Tension in Disease.—Villaret and Dufour report the application in various pathologic conditions of their method of studying the pulse by simultaneous oscillometry, palpation and auscultation. This provides a constant, the variations in which are characteristic and instructive.

Bacillary Dysentery Spread by Baker.—In the village of 600 souls there had been thirty-one cases of bacillary dysentery with six deaths in less than a month. The district health officer had visited the village and given the usual advice to disinfect the water, etc., and then left, but the military inspector investigated conditions more closely and found that all in the family of the village baker had had the disease among the very first. After the baker had been instructed and elementary hygienic measures enforced in his business, the epidemic was at once arrested.

Meningitis in Gonorrhea.—In the case reported by Boivin, violent headache and fever developed three or four weeks after the onset of gonorrhea. The urethral symptoms had been mild, but signs of inflammatory processes in the testicles, meninges and joints had followed, shifting about, like metastases. During the meningeal reaction, the lumbar puncture fluid was turbid but aseptic, and the polynuclears were intact. The meningeal symptoms were severe, suggesting epidemic meningitis, but the storm blew over in six or seven days, without leaving a trace. The young man had had epidemic meningitis four years before.

- *Jaundice in Scarlet Fever. P. Meurisse.—p. 63.

Roentgen-Ray Treatment of Cancer.—Regaud expatiates on the necessity for even irradiation throughout the whole of the cancer, and gives an illustrated description of how to realize this. Only by this means is the maximal effect induced with the minimum of chances for harm.

Jaundice in Scarlet Fever.—In the case reported by Meurisse the jaundice developed suddenly in the course of severe scarlet fever, the symptoms and retrospective diagnosis indicating a primary angiocholitis or angiocholecystitis coming on with the eruption. The jaundice and other symptoms subsided in a week without any special polyuria or azoturia.

*Inaugural Lecture of Obstetrics and Gynecology Course. G. Schickelé.—p. 61.

*Furunculosis. A. Mauté.—p. 64.

*Asthma and Anaphylaxis. P. Pagniez.—p. 65.

Obstetrics at Strasbourg.—Schickelé relates that the first manual on childbirth was published at Strasbourg (1513); the first school of midwifery was organized by Fried in 1728. It was maintained by the city as Fried had no connection with the medical school. Pasteur's first work was done at Strasbourg, and W. A. Freund there was one of the pioneers in the treatment of uterine cancer. Schickelé discusses the physiologic factors involved in producing delivery, saying that distant changes specific to pregnancy are evident in the pituitary, suprarenals and ovaries, but that we must not try to explain all the phenomena by the internal secretions alone.

Furunculosis.—Mauté has been studying vaccine treatment of furunculosis since 1900. He begins at once with a stock vaccine and follows it with an autovaccine, as the latter is always more effectual in warding off recurrence. In the usual adjuvant tonic treatment he warns against arsenic, as this drug seems to rather favor the staphylococcus.

Asthma and Anaphylaxis.—Pagniez reviews the literature on this subject, and on the treatment of asthma with an autoserum, or by desensitization with peptone or by digestive antianaphylaxis. Auld's method of intravenous or subcutaneous injections of peptone, Pagniez' method with peptone by the mouth, and Cordier's with peptone in enemas, are all effectual, but the benefit is short-lived. Hence they are inferior, he says, to the American method of gradual desensitization by vaccination. But the peptone methods are so simple and easy that they encourage further research and experiments in this line. He adds that in the most authentic asthma there may be a psychic element. The asthma with heart and kidney disease and emphysema is merely a form of dyspnea resembling asthma. In true asthma, the attack is a manifestation of anaphylaxis induced by the introduction into the system of some substance which acts as an antigen in the sensitized organism in contact with the substance inducing the anaphylaxis. This condition of anaphylaxis can be made to disappear, at least temporarily by appropriate treatment, even although the nature of anaphylaxis is still a mystery. The Americans cited are Meltzer (1910), Ramirez (1919), and C. Walker (1917 and 1918).

*Internal Treatment of Skin Disease. P. Ravaut.—p. 73.

*Functioning of Gastro-Enterostomy. G. Metivet.—p. 75.

Internal Treatment in Dermatology.—Ravaut declares that it is irrational to attack skin disease only from without. "Imagine any one treating the skin lesions of syphilis by local applications alone! And yet the dermatologist is too apt to focus his attention exclusively on the local process. He must be a biologist, not a mere botanist." By modifying the secretions it may be possible to break up the vicious circle, and he has often accomplished this with sodium cacodylate or sodium thiosulphate (hyposulphite) after failure of all local measures. He gives the cacodylate by the vein in a 10 per cent. aqueous solution, giving thus up to 15 or 20 gm. of the cacodylate in the course of three weeks. Some patients were given up to 40 or 50 gm. in two or three months. After improvement of the skin disease, small doses of the drug are kept up for some time to ward off recurrence.

In his experimental research on causes liable to augment the toxicity of arsphenamin, he confirmed the findings of others in regard to the importance of oxidations in this respect, and he found that sodium thiosulphate prevented or neutralized these oxidations. His further assumption that oxidations are an important factor in certain skin diseases was confirmed by the effect of this drug, sodium thiosulphate, on certain long intractable pathologic conditions in the skin. The skin cleared up promptly when the sodium thiosulphate was given by the vein in a 20 per cent. solution, in doses ranging from 4 to 15 gm. a day. He has also given it by the mouth in the same doses but with sugar; 25 gm. of sodium thiosulphate to 125 gm. each of syrup and distilled water. Fine results, he says, were obtained in urticaria, furunculosis, eczema and in arresting the arsenical abnormal redness and puffiness of the skin after arsphenamin treatment. In a case of pityriasis the skin slowly cleared up without any external treatment whatever.

Gastro-Enterostomy.—Metivet suggests that the condition of the stomach ought to be heeded more in making the gastro-enterostomy opening large or small. When there is atony of the stomach, the contents will pour out too quickly unless the opening is small, but it should be at the lowest point. With hypertony and necessity for resting the stomach, the opening should be large and in the antrum, near the lesser curvature. If conditions require it later, the pylorus can then be shut off.

*Streptococcus Septicemia with Jaundice. E. Quénu, G. Küss and M. Brulé.—p. 785.

Chilling Main Factor in Trench Foot. E. Chauvin.—p. 793.

*Mastoiditis and Pott's Disease. G. Portmann.—p. 808. To be cont'd.

*Wounds of Blood Vessels. N. A. Dobrovolskaia.—p. 848

Septicemia Simulating Bile-Duct Disease.—Quénu and his co-workers call attention to the difficulty of the differential diagnosis in cases such as the one described in which recurring attacks of fever with jaundice suggested angiocholitis except for the absence of gallstone colic pains. The woman of 67 had been having these attacks for over a month; the stools were not clay-colored, and tests for spirochetes were negative, but the general condition was growing grave and an operation was being considered when finally the streptococcus was found in the blood, clearing up the diagnosis. An abscess developing served for revulsion; after evacuation of the thick, fetid pus, recovery soon followed.

Mastoiditis and Pott's Disease.—Portmann declares that the connection between mastoiditis and tuberculous caries of the upper spine has not been sufficiently emphasized to date. He analyzes the anatomic and clinical relations, giving instances of suboccipital Pott's disease mistaken for mastoiditis, and vice versa, and the involvement of one region from the other. His long illustrated article is to be continued.

Traumatic Aneurysms, and Wounds of Vessels in General.—Dobrovolskaia tabulates the details of sixty-two cases at a

Petrograd hospital, and describes how it is possible to estimate the collateral circulation with an aneurysm by means of the sphygmomanometer records of the pulse below the aneurysm. The local, general and collateral blood pressure reveal the conditions in the circulation of the limb. Oppel argues that the vein must be ligated along with the artery, even when the vein is normal. This reduced circulation favors development of collaterals, he claims, but the experiences here related did not show any advantage from this in the eighteen cases in which it was applied. In one case there was aseptic gangrene of the leg muscles after ligation of the popliteal vein. The foot kept its normal aspect throughout, as the subcutaneous venous system had maintained the circulation.

*Mild Tuberculous Pleurisy. A. Dufourt and M. Ségard.—p. 545.

*Antitoxic Treatment of Typhus. W. Vignal.—p. 562.

*Apical Pleuritis. C. Roubier.—p. 576.

Recovery from Homicidal Delirium of Jealousy. R. Benon and P. Gouriou.—p. 587.

Mild Recurring Tuberculous Pleurisy.—Dufourt and Ségard ascribe to the exceptional energy of the defensive forces the atypical course of certain tuberculous processes in the lungs and pleura. In this article they refer in particular to what they call benign tuberculous corticopleuritis, with recurring foci, and to chronic congestions of the lungs of the so-called arthritic type. The foci and the physical signs change about in the former, and periods of latency intervene. A special feature of this form is the occasional intense pain, not paralleling the physical signs. Another feature is that the lesions gradually subside, never passing into the ulcerative-cheesy stage. They have encountered cases of this kind at all ages. The most constant symptom is the dyspnea. Patients complain of this even before the appearance of the pain. They get out of breath at every prolonged exertion, and this dyspnea persists to some extent even in repose, reflecting with some precision the intensity of the congestion in the cortex of the lung and in the pleura. After a climbing exercise, there may be paroxysmal dyspnea with a sensation of constriction of the chest, anguish and extreme tachycardia. Then for an hour or two the patient expectorates profusely, an actual alveolar serous effusion. In an hour or two the whole paroxysm is over. The pains that come and go throughout the whole course are of the dull, permanent neuralgia type, or like a set of needle pricks, brought on by laughing or coughing or abrupt movement of the chest. The asthenia, tenacious pains, hampered breathing, palpitations and tachycardia often entail neurasthenia in time in the rare cases presenting the complete clinical picture.

Dufourt and Ségard never found tubercle bacilli, but they explain the spurts of congestion as the result of local anaphylactic shocks to tuberculin manufactured in the lesions. Anything such as extra physical exertion, climbing, or injection of tuberculin, mobilizing the bacillary toxins in the focus, brings on this wave of congestive phenomena. The anaphylaxis gradually merges into immunity, and the symptoms finally subside completely. Sanatorium treatment and repose, revulsion to relieve the pain, and other physical measures to soothe the heart and reduce the tendency to congestions are indicated. High altitudes and exposure to wind are formally contraindicated. A weakly arsenical-sulphur water has sometimes hastened the cure when the acute phase is past. One patient improved with sea bathing on the Mediterranean coast in calm summer weather. Drugs, they say, are useless or harmful, except possibly calcium; some patients inclined to hyperacidity improved under alkalines.

Antitoxic Treatment of Typhus.—Vignal treated nineteen patients at Bucharest, with an exceptionally toxic form of typhus, with infusion by the vein in the twenty-four hours of 500 c.c. of a solution of 6.5 gm. sodium chlorid and 0.4 or 0.5 gm. chlorin to the liter. This was prepared according to Danielopol's directions by passing a current of chlorin through distilled water and adding the sodium chlorid. The chlorid content is determined with sodium hyposulphite,

Vignal found that the symptoms of profound toxic action became rapidly attenuated under these infusions. He analyzes his experience in detail, saying that the few deaths in the series occurred from pleurisy or streptococcus sepsis after the typhus had subsided, but the leukocytes still numbered 40,000. In one case the condition was not regarded as grave enough for the infusion as the leukocytes numbered only 20,000, but the fourteenth day they ran up to 23,400, and the infusion then came too late, the man dying the next day. The drop in the leukocyte count and the improvement of the other symptoms from toxic action followed promptly on the infusions.

Apical Pleuritis.—Roubier describes the sounds characteristic of pleuritis at the apex and their interpretation. In thirty of the fifty-three cases in this category, the auscultation findings were exclusively or predominantly restricted to the left apex. The condition has a favorable prognosis, whether of tuberculous origin or not.

*Varicella and Herpes Zoster. E. Feer.—p. 41.

*Legal Status of Abortion in Switzerland. P. Jung.—p. 42.

*Therapeutic Abortion. A. Gautier.—p. 46.

*Vernes Serologic Test for Syphilis. R. Preiswerk.—p. 51.

Chickenpox and Herpes Zoster.—Feer relates from the children's hospital at Zurich that a boy of 9 developed herpes zoster fourteen days after an infant in a connecting room had shown signs of chickenpox, and had been removed to another part of the building. The boy with herpes was not removed, and seventeen and twenty days after the onset of the herpes the two other children in the same room (three beds) developed chickenpox. The intervals thus from the first case of varicella were thirty-one and thirty-four days, and Feer thinks there can be no doubt that the herpes represented the second generation of the varicella, bridging the gap between the first and the two late cases. No other cases were known in the environment. In Bokay's compilation of thirteen cases, most of them from his own experience, the herpes was the first to appear, and the varicella developed secondarily, while in Feer's epidemic the varicella opened the sequence.

Legal Status of Abortion in Switzerland.—Jung suggests a rewording of the bill pending in the legislature to legalize therapeutic abortion and prevent abuses. He urges that therapeutic abortion should be ranked the same and be governed by the same laws as any operation. In the following article, Gautier, professor of penal law, discusses therapeutic abortion from the legal standpoint, and emphasizes that the presence of the third interested party, the *nasciturus*, imprints a unique stamp on abortion proceedings. But, he remarks in conclusion, whatever laws may be passed, conditions will continue the same: Good physicians will do what they think is right under the circumstances, and the unscrupulous will do as they please. *Les mœurs peuvent ici plus que la loi.*

The Vernes Colorimeter Serologic Test for Syphilis.—Preiswerk applied the Vernes technic in 1,200 cases and obtained parallel results to the Wassermann test in 76.7 per cent.; totally contradictory results in 1.1 per cent., and slighter divergence in the others. The technic is comparatively simple and easy, but the ingredients are not so constant as Vernes claims. Fresh pig serum is used instead of the rabbit amboceptor, and guinea-pig hemolysis is determined with a color scale. The organ extract is made with ethylene tetra chlorid acting on desiccated myocardium tissue from the horse.

Typhus During the War. G. Sampietro.—p. 620.

Cont'n.

Lice and Typhus.—Eight plates of the microscopic findings in lice confirm Alessandrini's statements as to prophylaxis of lice-borne diseases. The only rapid, practical and certain

means for extermination of lice, he reiterates, are with dry heat and with sulphurous anhydride. It is immaterial whether the latter is generated by burning sulphur or by the method he has found most convenient from the action of sulphuric acid on sodium thiosulphate (hyposulphite). He places the clothing to be deloused in a jar containing a 4 per cent. solution of commercial sulphuric acid. When the clothing is saturated throughout, he pours in double the amount of a 20 per cent. solution of sodium thiosulphate, and the contents of the jar are turned and shaken up together. An airtight cover is desirable, but not indispensable. The chemical reaction between the two fluids generates sulphurous acid gas, while the sulphur is precipitated on the insects, and is found deep in their respiratory organs, and the nits are killed at the same time. He adds that the cotton, wool, silk and linen articles, in seven different colors, used in his tests, kept in the fluids from ten to twenty minutes and then rinsed thoroughly in water, were not altered in their substance, and only a very few, after drying, were found to be slightly uniformly faded, especially the pink and yellow tints. His tests were made with both head and body lice, and with several types of similar parasites of the pig, etc.

*Whooping Cough. O. Cozzolino.—p. 113.

*Progressive Muscular Dystrophy. Giulio Milio.—p. 118.

*Influenza and Lactation. M. Rollandini.—p. 135.

Whooping Cough.—Cozzolino denounces the theory preached by A. Czerny that whooping cough is merely the form imprinted by a neuropathic predisposition on an ordinary catarrhal infectious process in the air passages. Czerny's pupil, A. Niemann, has recently presented what he thinks is further evidence to sustain this theory, namely, that when influenza swept through the infant asylum in his charge, nine of the sixty-two infants developed whooping cough as the acute stage of the influenza subsided. Cozzolino refuses to accept this evidence, as no search was made for the Bordet-Gengou bacillus in the throats. Although no visitors were admitted to the asylum, there might have been a carrier among the nurses. The scattered appearance of the whooping cough among the inmates merely confirms that all infants are not susceptible to whooping cough. On the other hand, the vanishing of the Bordet-Gengou bacilli from the throat after the fourth week of whooping cough; the recent success with prophylactic vaccination with this bacillus, and the development of antibodies in the vaccinated; the immunity conferred by one attack, and the possible transmission of the disease from the mother to the fetus, form a solid basis for assumption of a specific causal micro-organism.

Progressive Muscular Dystrophy.—Milio reports nine cases in children from 6 to 11 years old encountered in the last ten years. They represent the five types of this pathologic condition. No hereditary tendency was apparent, but the condition developed after an acute infectious disease in some of the children; after measles at 11 months in one, but in others no factors were known that could throw light on the origin.

Influenza and Lactation.—Rollandini concludes from the experiences at the children's clinic at Turin that there is no need to interrupt lactation if the mother has influenza. She should be encouraged to continue nursing the child, unless there are grave complications. But precautions should be taken against infecting the child. It should not be kept in the room with the mother, and should be brought in only for feedings. The nipples should be washed each time before giving to the child, and the mother should be warned not to speak or cough. She should hold a handkerchief over her mouth as long as the child is near. No resort should be made to artificial feeding unless absolutely necessary, and then only partially, if possible.

Cultivated Digitalis.—Gaglio reports the results of pharmacologic study of some cultivated *Digitalis purpurea* which demonstrated that it was as potent as the best from other sources. It requires an acid soil and protection against excessive heat.

Heredity in Cardiovascular Disease.—Galli remarks that few physicians seem to appreciate the frequency of the inherited tendency to cardiovascular disease in certain families. A number of instances from his own practice are compared with some on record. Rapid pulsation of the heart is often observed in several members of a family; he noted paroxysmal tachycardia in one man and in two of his children. What he calls hereditary myocardium is even more common, the subjects not able to stand as much physical exercise as others, panting after moderate exertion; the heart and the aorta are smaller than the average and the blood pressure lower. The young sometimes outgrow this under careful hygiene and progressive exercising, but exertion beyond what the subject can bear may do irreparable harm, as in a case described in which a mountain climbing excursion was too much a strain, and the young man died within two years. His father died a few years later of heart disease, and a sister at 13 from acute asystole. One brother of 16 is weak and tires readily and his heart is unusually small. Another younger brother has a more robust constitution but he too tires easily. The family tree of another patient shows the great grandfather dying of apoplexy at 70 and one of his sons at 64, while two other sons died of heart disease at 51 and 70, and the fourth of tuberculosis in childhood. In the six children of the third generation one died at 41 of heart disease, three of cerebral hemorrhage at 51, 46 and 45, and the others of tuberculosis or Adams-Stokes disease. One of the thirteen great grandchildren has a cylindrical thorax. Galli has been preaching for years the importance of compiling data on heart disease, following the cases decade after decade and investigating the family tree. The military systems of the world have it in their power now, he continues, to inaugurate and carry out this systematic and organic study of pathologic conditions in the circulatory system, amplifying and continuing the work done during the war in this line. By this means positive data will be accumulated to offer to hygienists and legislators for prophylactic action.

*The Intermediate Metabolism in Nephritis. A. Barlocco.—p. 1041.

Paratyphoid A in Macedonian Campaign. C. Vallardi.—p. 1046.

Neurosyphilis and Predisposing Factors. G. Pighini.—p. 1050.

*Prophylaxis of Renal Tuberculosis. D. Taddei.—p. 1056.

The Metabolism with Uremia.—Barlocco reports ten cases of nephritis studied by Bang's micromethod, including one of so-called pseudo-uremia and one of uremia with convulsions. In both of these latter cases the blood and urine findings were normal for a time after the symptoms had developed. Only later came the period with evidences of profound derangement of the nitrogen metabolism. In the eight other cases the uremia seems to be merely from retention of nitrogenous waste, but in two of these latter cases there seems to be a primary exaggerated production of nitrogenous waste in the tissues, and the excess passes only tardily into the blood and urine. These cases confirm Maragliano's theory that primary or secondary lesions in the tissues may be an important element in the clinical picture of nephritis. They also sustain the analogy between uremia and the toxicosis from splitting of albumin. Even in some of the other cases there were certain features suggesting increased production of waste, in addition to the decreased elimination. In still another class of cases, he adds in conclusion, the uremia may be traced to changes in

the vessels alone, and the metabolism is not a direct factor, or has merely a slight, secondary influence.

Prophylaxis of Renal Tuberculosis.—Taddei asserts that renal tuberculosis is widely prevalent and that it almost always escapes detection, at least during the period when a nephrectomy offers the greatest chance of success. It is an essentially chronic disease, and it may develop insidiously with periods of remission. One of his cases was inoperable from bilateral pyonephrosis when first seen, but the patient is still under observation ten years later. The first, the albuminuric phase, is followed by the pyuric phase, with or without slight symptoms from the bladder. The involvement of the bladder forms the third phase. Usually it is only after the practitioner has wasted some time trying to cure the "cystitis," that he thinks of the kidney and calls in a surgeon, just before the fatal progression into the fourth, the terminal stage. Renal tuberculosis is of blood-borne origin, Taddei reiterates, and every young person with albumin and pus or blood in the urine (not explainable by gonorrhea or other infectious disease or adnexitis), should be suspected of renal tuberculosis even although the general condition is good. Note the transparency of the urine, the tender points for the kidney, palpating for them with the hands superposed, working from above downward and from within outward along the line from the umbilicus to the thigh, following the pulsation of the iliac artery down to the passage of the ureter into the superior strait of the pelvis. An absolute diagnosis is possible only with discovery of the tubercle bacillus, and with this, the surgeon should be called in at once. Krönlein found a tuberculous process in the kidney in 29.8 per cent. of the cadavers examined, and all authors agree that renal tuberculosis is unilateral in the first stages in 88 per cent. of the cases at least. By the time severe cystitis has developed, both kidneys are usually involved.

Archivos Españoles de Enf. del Ap. Digestivo, Madrid

November, 1919, 2, No. 11

Diagnosis of Gastric Cancer. T. Hernando.—p. 641; Idem. J. González Campo.—p. 645.

*Gastric Ulcer. L. Urrutia.—p. 676. Idem. F. Gallart and F. Ribas.—p. 702. Idem. C. G. Peláez.—p. 705.

*Remote Results of Gastro-Enterostomy. J. MacDonald and W. A. Mackay.—p. 726.

Gastric Ulcer.—This entire issue of the *Archivos* is devoted to the transactions of the subsection on disease of the digestive apparatus at the First National Medical Congress in Spain last spring. Urrutia insists that international statistics show that ample resection of the stomach does not have a much higher death rate than simple gastro-enterostomy while the results are incomparably better. In a recent series of 82 cases of resection the mortality was 4.8 per cent., these patients succumbing to acute dilatation of the stomach, pneumonia, paralytic ileus or chloroform jaundice. In a previous series of 117 cases the mortality was 6.6 per cent., while it was 6 per cent. in 115 gastro-enterostomy cases. He mentions C. Alvarez' proposal to treat gastric ulcer by stretching the fifth, sixth and seventh intercostal nerves on both sides and resecting the fifth. This may be useful with rebellious hyperchlorhydria, but seems irrational for an already established hard ulcer.

Gallart and Ribas say that the cicatricial changes found in the pylorus and elsewhere in the stomach testify that gastric ulcers can and sometimes do heal spontaneously. They applied Alvarez' nerve stretching technic in 2 cases, but are unable to pass a decisive judgment on it. In only 8 per cent. of their gastric ulcer cases were conditions favorable for an operation; in all the others there were adhesions, multiple ulcers in 12 per cent., and extensive and intense gastritis was the rule. They state that the mortality from resection is from 20 to 30 per cent. in general, while gastro-enterostomy has a death rate of only 3 or 4 per cent. and definite results are realized in 65 per cent. of the cases. In 2 of their cases cancer developed later. When there were disturbances they were almost always from growing up of the new opening, or from peritoneal bands, or adhesion to the pancreas, or irreparable lesions of the gastric glands. Peláez' mortality in 128 gastro-enterostomy cases was direct in 2.14

per cent.; total, 11.42 per cent. In 37 of his 140 peptic ulcer cases, the lesion was in the duodenum.

Gastro-Enterostomy.—MacDonald and Mackay report 1.27 per cent. mortality in 314 gastro-enterostomy cases. In 6 of 19 cases of ulcer on the lesser curvature the operation brought little if any relief.

Temporizing with Extra-Uterine Pregnancy. Vital Aza.—p. 220.

Malaria in Morocco. J. A. Romera y Domingo.—p. 228.

Renal Tuberculosis.—Barragán affirms that medical treatment of renal tuberculosis should be considered only when operative measures are out of the question, but heliotherapy and other general measures are useful adjuvants at all stages. He declares that one is safe in removing the kidney for unilateral renal tuberculosis when the Ambard constant is good, even when it is impossible to explore the bladder. But as a rule, catheterization of both ureters is the only means for a positive diagnosis of whether one or both kidneys are affected. When both are involved, nephrotomy of one and nephrectomy for the other may give unexpectedly favorable results.

Thyroid Insufficiency After Influenza.—López Albo has reported two cases of extreme somnolency and headache after influenza, cured or materially improved by thyroid treatment. He here describes a third case in which the postinfluenzal hypothyroidism took the form mainly of neuralgias, which disappeared likewise under thyroid treatment. This patient was a man of 35.

*Metrorrhagia in Virgins. M. Costales Latatú.—p. 350.

Certain Dermatoses of Pregnancy.—Pardo reviews the types of herpes, molluscum and impetigo peculiar to pregnancy, and comments on the grave prognosis with the latter as it is a sign of septicemia. With other dermatoses frequent in pregnant women, he warns against the use of starch in powders, especially for eczema of the vulva as the vegetable granules ferment readily. An 8 per cent. solution of aluminum acetate or diluted Burrow's solution helps to dry up oozing eczema in this region. Pruritus requires treatment of the causal autointoxication, restriction to a milk diet, and sedatives. Local measures give only transient relief, but a chloral lotion or cocain salve, or touching with silver nitrate may be indicated. The roentgen rays, $\frac{1}{4}$ H. twice a week may reduce the pruritus and cure it completely in two or three applications. Pardo warns against the factitious dermatoses of hysteria: "Note the regularity and symmetry of the lesions, the fact that they occur only on regions readily reached by the hands, and the track of a drop of caustic running down."

Metrorrhagia in Virgins.—Costales relates an extreme case in which the robust girl of 18 had been almost exsanguinated by two months of persisting uterine hemorrhages. She had been given iron, cod liver oil, etc., without avail, but under ovarian treatment the hemorrhages ceased and she soon recuperated. Polyglandular treatment proved effectual in

some other cases of the kind, but this young woman had two relapses under polyglandular treatment. The improvement became constantly progressive only after the ovarian treatment alone was pushed.

Cesarean Section for Placenta Praevia and for Eclampsia. J. A. Ortiz.—p. 595.

*The Arterial Tension in Tuberculosis. Amador Guerra.—p. 604.

Bronchopulmonary Spirochetosis.—Méndez has encountered one acute and three chronic cases of Castellani's spirochetosis in eastern Cuba. The diagnosis in all had been pulmonary tuberculosis until corrected by discovery of the spirochetes in the sputum and the absence of tubercle bacilli. Under arsenic treatment, the spirochetes disappeared in the acute case and the chronic were much improved, and some recovered completely under this treatment.

Arterial Tension in Tuberculosis.—Guerra comments on the favorable prognosis when the arterial tension in tuberculosis is found normal or above. A sudden rise in the blood pressure is liable to induce hemoptysis. A sudden drop is a sign of acute exacerbation or generalization of the process. The habitual low pressure in the tuberculous may be explained by bacterial toxins or by suprarenal insufficiency.

The Internal Secretions in Relation to the Skin.—De Oyarzabal reviews this large field, telling of the various data accumulated by different clinicians in this line. In his own practice, as scleroderma developed in one girl of 18, menstruation stopped. Others have reported similar experiences, and have noted the relative frequency of scleroderma with symptoms of the menopause. He cites Sabouraud's theory that alopecia is traceable to the excessive internal secretion of the sexual glands. In seborrheic alopecia, the secretion of sebum is excessive, and this does not occur until the sexual glands are developing. "Children never have seborrhea." The question of the relations between the endocrine and the sebaceous glands may repay study and may throw light on baldness. Organ extract treatment is justified in all cases of disease of the skin or appendages in which endocrine deficit is suspected. But we are disarmed with disease traceable to excessive functioning of endocrine glands, unless we can learn to stimulate the antagonist glands. Some have reported favorable experiences with mesenteric gland extract in treatment of scleroderma, and others with epinephrin in erythromelalgia. In one case the vasomotor disturbances in hands and feet for twelve years subsided under suprarenal treatment.

The Diagnostic Value of the Glycemic Reaction.—Hahn and Offenbacher remark on the great value for practical diagnosis of the behavior or "reaction" of the blood sugar in response to a definite, uniform test meal: The blood sugar value was determined fasting. Then 50 gm. of glucose were given in 300 c.c. of tea. Every hour the urine and the blood sugar values were determined, with care to prevent the patient from eating or drinking anything, or moving about too much, during the experiment. This moderate dose (50 gm.) was used because it would be readily absorbed and furnish distinct differential values. It was also feared that diabetics might be harmed by larger doses. Double determinations were made which agreed very closely, as a rule. Bang's iodine micromethod was used for the determinations. The experiment was applied to healthy subjects as well as to patients with various diseases. The results are shown in glycemic-reaction curves. The writers give up to 0.11 per cent. blood sugar as the normal figure, fasting; values from 0.12-0.16 per cent. they designate as slightly above normal or suspicious, and a sugar content of more than 0.16 they characterize as pathologically hyperglycemic.

Botulism.—Three different outbreaks of botulinus poisoning in Kiel within a year, which resulted in three deaths, induced Bitter to study into the question. The eating of salted herring caused the first of the three fatal cases. The herring had a typical rancid odor, and *Bacillus botulinus* was cultivated from two herring. Others fed to mice exerted a toxic effect. Too little vinegar had been used in preserving them, the pickle containing only 0.6 per cent. acetic acid. Experimentation showed that botulinus strains of various origin grew almost unchecked in nutrient agar containing up to 0.1 per cent. acetic acid. It was found, however, that a pickle containing 2 per cent. or more of acetic acid would prevent the development of poison from *B. botulinus*. It has also been shown that a 10 per cent. brine, such as is usually employed, will protect food preserved in it against the botulinus. The second outbreak in Kiel, comprising four cases, resulted from the eating of rancid-smelling raw ham. There were no fatalities, although the cases were typical and severe. In the third outbreak three persons were affected by eating salted herring, and two of these died. Bitter recommends that in the case of meat, fish and sausage poisoning all manifestations resembling botulism should be made reportable by law. He places the case mortality from botulinus poisoning in Germany at 16 per cent. Greater publicity should be given to the fact that if preserved vegetables and meats have a peculiar disagreeable odor, taste or appearance there is great danger in their consumption, and that if they are used, though they look suspicious, they should be thoroughly cooked, though it is true that cooking sometimes fails to protect. As a rule, *B. botulinus* is found only in food carelessly preserved or stored in too warm a place. Bitter knows of only one instance in which *B. botulinus* has been isolated from other than damaged foods. Kempner and Pollack succeeded in isolating *B. botulinus* from the feces of pigs.

Tendon Transplantation in Radial Paralysis.—Operations on the nerves in radial paralysis having failed to accomplish the expected results, Gaugele thinks that Perthes and others have done a good service in reintroducing the method of tendon transplantation. Tenodesis, as recommended by Perthes, may be indicated if the paralyzed muscles look pale or yellow, but ordinarily he thinks it can be dispensed with, since the operation is thus made more complicated. He does not approve of separating the paralyzed muscles from the tendons, as he finds that such muscles often recuperate when put to work. In place of Perthes' method of uniting

the flexor and extensor muscles, he prefers Vulpius' button-hole method. The distribution of the flexor muscles is best made, he thinks, in the direction that the extensor muscles run, that is to say, the flexor carpi ulnaris is attached to the extensor communis and extensor pollicis longus, and the flexor carpi radialis to the other muscles of the thumb. The extensor carpi ulnaris and the extensor carpi radialis longus may, likewise, be attached to the flexor muscles.

Radical Operation for Inguinal Hernia in Infant.—Schmidt reports an operation for inguinal hernia on a 10-month-old infant. Some of the noteworthy features of the case were the presence of the appendix in the hernial sac (especially strange in an infant); repeated inflammation of the appendix in the hernial sac, and the favorable course, which supports the view that inguinal hernia should be operated on in earliest childhood. If the operation had been postponed, the child would have been continually exposed to incarceration of the hernia and to appendicitis. A truss might have aggravated the danger from appendicitis. The operation was performed without anesthesia and was borne well in spite of the fact that the infant was not sturdy.

*Traumatic Aneurysm in the Liver. K. Kädig.—p. 82.

*Exuberant Callus. P. Sudeck.—p. 105.

Keloids Without Known Cause.—Freund describes a case which not only throws light on the origin of keloids, but points the way to effectual treatment. The keloids developed spontaneously on the man of 31, different ones presenting the features of all known varieties of primary and secondary keloids. There was always some local defect of the skin that invited the keloid, but the keloid growth did not develop at every defect. He seemed to display both a general and a local predisposition for the development of keloids. Freund accomplished the cure by excision into sound tissue and then exposing the field, without suturing, to the roentgen rays, up to the erythem dose, allowing only two or three days to elapse before beginning the raying. No effect was apparent from radium treatment of some of the keloids. He has applied this operative plus postoperative irradiation in nine cases to date, and all seem to be permanently cured.

Inguinal Hernia.—Drüner compares the various technics in vogue for correction of inguinal hernia, and gives an illustrated description of the modified Hackenbruch operation. He has applied it with superior results in 509 cases of inguinal hernia, all in hard-working men in a coal mine district. The hernia returned after the Bassini operation in 21.4 per cent. but after his modified technic in only 4 per cent. It aims to give the spermatic cord more room while insuring the greatest solidity in the region.

Trophic Changes After Injury of Nerve.—Breslauer has been studying on himself, on men with war wounds of nerves, on other patients, and on dogs, the local effect of heat or of mustard oil applied to the area innervated by a damaged nerve. The region loses in a few weeks the capacity to react with active hyperemia to irritation from heat, mustard oil or other stimulus. This suggests that the lack of this normal hyperemia defensive reaction allows irritating factors to injure the skin, and thus to set up processes which we call trophic changes. They are thus essentially the result of defective conditions in the circulation, and the nerve injury is responsible for this. Breslauer's experiments showed further that although the capacity was lost for active hyperemia reaction to the irritation from the mustard oil, etc., yet the capacity for vasoconstriction under the application of cold or epinephrin persisted unimpaired and indefinitely. He theorizes to explain this opposite behavior of the vasodilating and constricting apparatus. The skin does not redden under mustard oil when all sensation has been abolished by nerve blocking. As sensation returns, and the area begins to smart, it begins to turn red too. But the vasoconstricting action of epinephrin proceeds the same whether there is sensation in the region or not.

Aneurysm in the Liver.—Kädig summarizes forty-two cases of aneurysm in the hepatic artery, all fatal but one, and four cases in which the aneurysm was inside the liver, all fatal. In a personal case the aneurysm had developed after a gunshot wound, and it had opened into the gastrointestinal tract, but the man recovered after ligation of the hepatic artery. The circulation of the liver is still adequate as the complete recovery in this case testifies, confirming the results of ligation of this artery in dogs.

Exuberant Callus.—A scrap of periosteum torn off may explain the tendency to excessive production of callus in certain cases, Sudeck explains, with roentgenograms of some typical cases demonstrating this etiology. They disprove the theory of traumatic ossifying myositis as responsible for redundant callus around the bone.

*Mammary Cancer and Postoperative Raying. G. Perthes.—p. 25.

*Differential Pressure Mask for Empyema. O. Goetze.—p. 29.

*Reconstruction of Urethra. W. Budde.—p. 32.

Mammary Cancer.—Perthes compares the ultimate outcome in 88 cases of mammary cancer rayed after mamnectomy, with 130 cases not given the postoperative irradiation, and 70 cases in which only inadequate exposures were made. There was recurrence within a year in 41 per cent., 28 per cent. and 38.5 per cent. in these groups respectively, but among the recurring cases there was no local recurrence in 18, 11 and 11 per cent., respectively. These figures speak decidedly against any improvement of the statistics from the postoperative raying. The recurrences within a year were almost twice as numerous as in the unrayed cases, and the deaths from internal metastasis without local recurrence were four times as numerous.

Mask for Differential Pressure in Treatment of Pleural Empyema.—Goetze refers to after-treatment when the aim is to realize expansion of the long compressed lung. The mask he has constructed for the purpose is just the reverse of Kuhn's aspiration mask, as inspiration is free and only expiration is checked with an adjustable valve. The mask has been worn day and night by various patients, and complete expansion of the lung resulted even under the most unfavorable conditions. The mask is also useful during resection of ribs and other operations on the thorax.

Subcutaneous Pedunculated Skin Flaps.—Budde describes his technic as applied in reconstruction of the urethra, although he says it can be applied to any passage or area. He also asserts that it is based on a new principle, namely the use of a square of skin, the sides sutured together to form a tube, while enough subcutaneous tissue is taken up with the skin to permit of suturing without the needle passing through the epidermis. The subcutaneous tissue below the lengthwise center of the flap is not severed so the skin tube is pedunculated its entire length. The flap for the urethra is taken from the lower aspect of the scrotum; it is about 3 cm. wide and the peduncle is thus formed by the septum tissue. The tube thus formed over a large catheter is then worked through a tunnel dug for it under the skin to the gap in the urethra, exposed through the perineum. As the tube is drawn through the tunnel, its "mesentery" is dragged along with it. The tube is turned over endwise to be drawn through, to bring the suture on top. Depilation of the skin of the scrotum is usually a necessary preliminary from fear of incrustation of hairs. The reconstruction of the urethra by this technic can be accomplished at one sitting, thus providing an epithelium-lined, strong and almost normally nourished tube. Flaps with this subcutaneous pedunculization might be utilized to repair defects on the cheek, etc.

*Latent Microbism of the Vagina in Relation to Leukorrhea. A. Loeser.—p. 46.

*Local Injection of Turpentine in Treatment of Adnexitis. A. Fuchs.—p. 52.

Obstetric Injury of the Brain.—In the first two of the three infant cadavers described there was extensive hemorrhage in the ventricle. The hemorrhage evidently proceeded from the deep cerebral vein. Undue stretching of the corpus callosum would explain this, and also the laceration of the tentorium sometimes observed. In the other cadaver the findings were those of patches of softening of the brain, probably the result of ischemia from vascular spasm. Kruska has compiled twenty such cases. The child seemed to be normal at first. Then left hemiplegia developed, and finally hemorrhage in the affected region of the brain, with death the twelfth day.

Ovarian Tumors with Pathologic Pregnancy.—In Fraenkel's case a tumor had developed in each ovary along with the teratomatous fetus in the uterus, with hydramnion. After expulsion of the macerated fetus at the sixth month the ovarian tumors gradually retrogressed. Conditions thus were like those in fifty cases on record in which ovarian tumors developed with vesicular moles, and retrogressed after their expulsion. In the roentgen study of this case the advantages of preliminary injections of oxygen into the abdominal cavity were striking.

Jan. 10, 1920, 41, No. 2

*Micro-Analysis of the Blood. J. Feigl.—p. 17.

Micro-Analysis of the Blood.—Feigl suggests other lines in which Bang's micromethod can be instructively applied, with slight modifications, as in Ljungdahl's research on volatile substances in the blood. The latter uses capillary tubes for the weighing procedure, instead of Bang's paper, for determination of the acetone in the blood. This capillary technic has a certain number of advantages for research of different kinds in this line, especially for analysis of lipoids. Instead of Bang's paper, Feigl uses asbestos fibers. They take up the blood as well as the paper, and allow estimation of the ash and even of its separate elements. Extremely small quartz beakers with platinum loops, and platinum iridium beakers—eventually filled with loose quartz—also answer the same purpose. Another field for research is with microcolorimetry. Feigl has succeeded in this way with extracts from as little as 200 mg. of blood. Determination of cholesterol is possible also with this technic. Picric acid reduction of sugar is another progress. In short, he concludes, "the reactive instrumental and theoretical possibilities of colorimetry and the wonderful nephelometric findings open prospects of applying Bang's fundamental principle in untried fields which promise great progress." (Nephelometry is the method of analysis by measuring the brightness of light reflected by particles in suspension in a tube.)

*The Freezing-Point of the Blood in Diabetes. A. Lippmann.—p. 41.

Low Freezing Point of the Blood in Diabetes.—Lippmann calls attention to the lowered freezing point of the blood in eleven diabetics examined. In six of the eleven cases the freezing point was between -0.59 and -0.62 C., instead of the normal -0.56 to -0.58 . The intensity of the glycosuria or glycemia did not parallel the drop in the freezing point. This permanently abnormal freezing point indicates, he declares, some disturbance in the mechanism regulating the osmotic tension of the blood, and that other reducing substances, besides the glucose, are retained in the blood.

Recurrence of Scarlet Fever. M. W. Marsman.—p. 1955.

Reform in Medical Teaching.—Van Rijnberk's article was summarized in these columns, March 20, p. 838.

Cancer in the Esophagus.—The age (25), the long duration, and the survival for fifteen months after a fistula had been made into the stomach, the metastases in the skin, and the

absence of metastases in organs nearby were special features of the case reported by Praag and Benjamins, as also the shortening of the esophagus. It measured only 16.5 to 19 cm. from the cricoid to the cardia, while the normal figure is said to be from 23 to 30 cm.

Cataract and Syphilis.—Smit recalls that potassium iodid and other drugs have been given empirically in treatment of cataract, but all except potassium iodid have been abandoned, and the absolute inefficacy of internal treatment has been proclaimed by Fuchs and others. Undaunted by others' experiences, Smit gave potassium iodid systematically to 6 patients with cataract. No benefit was apparent in 4 cases but in the 2 others marked improvement followed. The improvement in 11 other patients treated with mercury was pronounced in all and was most striking in some cases. All these patients have been under observation for several years; as also other cases not included in these statistics. The mercury was given intramuscularly every day; 0.01 c.c. in the form of the peptonate, in 3 c.c., plus 0.05 c.c. sodium cacodylate in 1 c.c. subcutaneously.

Was Influenza Pneumonia Contagious? K. Motzfeldt.—p. 165.

*The Leukocyte Count in Influenza. R. Bache.—p. 176.

Endemic Oxyuriasis. M. Solberg.—p. 184.

*Carcinoids in Appendix. K. Nicolaysen.—p. 186.

Malformation of Clavicles and Skull.—Yttri has compiled considerable literature on congenital deformity of the clavicles, and describes an extreme case of cleidocranial dysostosis in a man of 66, and two similar cranial cases. The tendency to this malformation has been noted through two and three generations. Gegenbaur has reported a case in which a woman with this deformity transmitted it to her children by two different husbands; some of her children were normal. This type of dysostosis may affect the clavicles alone or the skull alone, but the two are generally combined, and there were often other bone deformities. The cleidocranial anomalies form a special type, although certain features suggest rachitis, inherited syphilis, etc. Puberty is late but not impaired. The anomalies seem to be of the mutation type, as de Vries uses this term for plants. That is, the changes appear apparently spontaneously and are transmitted to the offspring, but disappear by cross breeding. Among the 70 cases on record, 20 were reported from Germany and Austria, 15 from France, 9 from Sweden and 6 from North America.

The Leukocyte Count in Influenza.—Bache found leukopenia the rule in his influenza cases, but the leukocyte count ran up when empyema developed. In influenzal pneumonia, the death rate was lowest in the group with high leukocytosis.

Carcinoid in Appendix.—Nicolaysen reports three cases in women and two in men, and remarks that these carcinoid tumors certainly do not belong in the carcinoma group. In two of his cases the symptoms had been those of acute appendicitis; in one, of chronic appendicitis, and two had never caused any symptoms.

BASAL METABOLISM DETERMINATIONS IN GENERAL INTERNAL DIAGNOSIS

CLINICAL APPLICATION, WITH ILLUSTRATIVE CASES

G. W. McCASKEY, M.D.

Professor of Medicine, Indiana University School of Medicine
FORT WAYNE, IND.

Basal metabolism determinations have been placed on a practical clinical basis by the Benedict¹ method. The general physiologic and clinical significance of fluctuations in the metabolic rate is now also well understood. The next step is for clinicians to work out the range and value of their clinical application in suitably selected cases in routine diagnostic work. This is really the "touchstone" of any diagnostic method. Unless its clinical value can be shown to be commensurate with the time, labor and equipment required, and in this instance these items are rather large, it cannot and should not endure. This paper is offered as an additional contribution to this end.

It may fairly be said that the basal metabolism test rests on an established scientific basis. The main facts were quite fully understood for a quarter of a century before they became clinically applicable outside of institutional work. There is little that is new except the introduction of clinically practical methods.

This method of investigation involves more than simply the thyroid problem. The entire endocrine system, as yet so little understood and so difficult of interrogation, is involved, and stands in pressing need of both clinical and scientific investigation. It is not, indeed, limited to the endocrine system, as a careful consideration of all the facts will make perfectly obvious. For instance, if the thyroid gland is completely removed, the basal metabolism drops only 40 per cent. below the average normal, where it remains substantially constant. The question as to what keeps the basal metabolism up to this level instead of dropping to zero, considerably short of which would be death, is discussed by Kendall.² While it is not fully understood, he believes that amino-acids, proteins, creatin, creatinin, and probably other substances, play an important rôle in the stimulation and regulation of the basal metabolic rate. There seems to be no doubt that other members of the endocrine system play with thyroxin a synergistic rôle, while, of course, other bodies known and unknown, with entirely different physiologic effects, may have to be considered. This is undoubtedly true of the suprarenals. Tompkins,

Sturgis and Wearn,³ for instance, have shown that there is a marked increase in the basal metabolic rate, after the hypodermic administration of 0.5 c.c. of 1:1,000 solution (about 0.5 mg.) of epinephrin, amounting to 15 or 20 per cent. The modus operandi of epinephrin in the production of increased basal metabolism is probably quite different from that of thyroxin, and the effect is strikingly less in degree. These investigators attribute to the effect of epinephrin on the sympathetic autonomic nervous system the tremor and increased general muscular tonicity, the disturbed carbohydrate metabolism, and in some cases—but not all—the increased cardiac activity.

There is also the possibility that other endocrine hormones aside from the thyroid produce their effect on metabolism indirectly through the thyroid by neuro-circulatory influences on the thyroid gland. Thyroxin, on the other hand, according to Plummer,⁴ acts directly on all body cells. What has been said of the effect of epinephrin on the metabolic rate is probably true, though to a much smaller extent, of the pituitary, parathyroid, and pancreatic internal secretions.

A careful review of all the facts will, I think, convince any one that the one important controlling factor in the regulation of basal metabolism is thyroxin, on which the functional activity of the thyroid gland is largely, if not altogether, dependent. We are entirely ignorant at present of the identity of any other toxic substance, though some think there may be modification of the thyroxin molecule in some cases of exophthalmic goiter, or possibly even other endocrine hormones synergistic with or quite dissimilar to thyroxin.

The important question bearing on this clinical study is the dependability of fluctuations of the basal metabolic rate as an indication of thyroid activity; and this would obviously depend on whether the modified thyroxin molecule, if such exists, or possibly other unknown hormones, would retain the specific autocoid effect of the thyroxin molecule on cellular metabolism, or might possibly produce other toxic phenomena. Perhaps we cannot be too dogmatic on this point at present; but while recognizing the paramount position of the general clinical judgment in every case, variations in the metabolic rate as indirectly determined by the oxygen consumption must be regarded as the most scientific and practical index of thyroid toxicity.

In what group or groups of cases are the routine determinations of basal metabolism worth while? In general, this question may be thus answered:

1. In all cases of definite goiter, and especially if associated with health disturbances, to ascertain the degree, if any, of its toxicity.

1. Benedict, F. G.: A Portable Respiration Apparatus for Clinical Use, *Boston M. & S. J.* **178**:667 (May 16) 1918.
2. Kendall, E. C.: The Thyroid Hormone and Its Relation to the Other Ductless Glands, *Endocrinology* **2**: 81 (April-June) 1918.

3. Tompkins, Edna H.; Sturgis, C. C., and Wearn, J. T.: Studies on Epinephrin, *II. Arch. Int. Med.* **24**: 269 (Sept.) 1919.
4. Plummer, H. S.: The Function of the Thyroid, Normal and Abnormal, *Tr. Assn. Am. Phys.* **31**: 128, 1916.

2. In a large group of cases either with or without goiter, with symptoms resembling, either closely or remotely, those of thyrotoxicosis.

In regard to the first group, whenever a patient has a goiter, large or small, and there is impairment of general health, whether the symptoms are typical of thyrotoxicosis or not, the toxicity of the goiter should be ascertained by the determination of the basal metabolism. This is especially true when considering the necessity for and character of therapeutic measures, surgical or medical. In any case with a goiter requiring a general diagnostic study, this accurate index of goiter toxicity should not be neglected. In judging of the operative risk in thyroidectomy, it is of the first importance. It appears to be true that this risk increases to an appalling degree when the metabolic rate attains an increase of around 100 per cent. Non-surgical measures should be exhausted in such cases in an effort to reduce the metabolic rate before operation, if the latter is decided on. The success of therapeutic measures can now for the first time be accurately gaged by basal metabolism determinations, instead of depending on the notoriously unreliable clinical data, such as pulse rate or nervousness.

Equally important, and presenting great diagnostic difficulties, is the second group indicated. It does not matter much in the final judgment whether the patients have or have not a palpable thyroid. I have seen several cases in which the thyroid was very doubtfully palpable, with the metabolic rate increased more than 50 per cent. Much more important than the goiter is the history of the case and the character of the symptoms. Among the symptoms suggesting investigation along these lines may be mentioned:

1. Psychoneurotic disturbances.
2. Circulatory disturbances:
 - (a) Tachycardia or bradycardia.
 - (b) Cardiac myasthenias.
 - (c) Certain arrhythmias.
3. Fine tremors.
4. Hyperhidrosis and hypohidrosis.
5. General debility.
6. Loss of weight.
7. Slight temperature disturbances.

Not one of the foregoing symptoms can be regarded as strongly diagnostic, much less pathognomonic, of hypothyroidism or hyperthyroidism. In fact, it is perhaps not too much to say that if the majority or perhaps even all of these symptoms were present in an individual case, it would still be possible that the syndrome could be due to something entirely aside from thyroid disease.

As a matter of course, if with these symptoms there are found a goiter and exophthalmos, the diagnosis of thyroid disease should be considered established. With the goiter alone this would not be so obvious, because if these symptoms, singly or collectively, can be due to causes other than thyroid disease, the presence or absence of a goiter would really prove nothing, although creating a strong presumption in favor of hypothyroidism or hyperthyroidism to be verified by subsequent investigations.

It is probably unnecessary to comment at length on the individual symptoms enumerated above. Taking, for instance, such of the symptoms as psychoneurotic instability and tachycardia, which may be regarded as the most characteristic symptoms of the thyroid syndrome, it is perfectly obvious that they may be due to

causes of the most diverse character. Nervous or mental overstrain, various chronic infections, but especially syphilis and tuberculosis, and a great variety of pathologic conditions occurring in the various glandular organs of the body, malnutrition, from whatever cause, gastro-intestinal disturbances, and many other conditions must be kept in mind as possible explanations of such a symptom group. Their differentiation from thyrotoxicosis can usually be made with a certain degree of probability by the general clinical picture and the usual diagnostic methods for the recognition of these pathologic conditions. The final court of appeal, so far as the thyroid problem is concerned, however, is the determination of the basal metabolism, which furnishes the most reliable proof either for or against the existence of thyroid disease.

The following cases are selected because in them the metabolic rate furnished a more or less decisive factor in the diagnosis, which could not have been ascertained in any other way. In most, or perhaps all of these cases, unlike the outspoken cases of exophthalmic goiter or myxedema, the disturbances of metabolism that are always largely determined by thyroid activity were masked by or associated with other conditions which obscured the clinical picture. This, in fact, is the very reason why these cases are selected, in order to illustrate the practical clinical value of these methods.

REPORT OF CASES

CASE 1.—Hypothyroidism and tonsillar infection.—History.—Mrs. L., aged 28, complained of nervousness, general pains and enlargement of the neck. An older sister had goiter, but was now symptomless. In April, 1918, the patient had tonsillitis, followed in two weeks by "rheumatism." She had enlargement of the neck for many years, since she was 14; "misery" in the neck began about one year before I saw her; soon followed by general pains. She was in bed with "rheumatism" for three or four days, and had occasional "rheumatic" pain for several weeks afterward. She had "nervous" headaches, and became dyspneic when excited or on exertion. The goiter was symptomless until one year before when she had some pain up and down the spine and the back of the neck, and since then the goiter had annoyed her considerably. There had been no increase in size for a number of years.

Physical Examination.—The pulse was 72; the blood pressure, 135 systolic and 100 diastolic. There was a very slight tremor of both hands. The tonsils were moderately enlarged and cryptic. The urine was negative. Blood examination revealed: hemoglobin, 85 per cent.; red blood cells, 3,731,000; white blood cells, 7,200; polymorphonuclear neutrophils, 60 per cent.; small lymphocytes, 27 per cent.; large lymphocytes, 10 per cent.; transitional cells, 1 per cent., and eosinophils, 2 per cent. The Wassermann reaction was negative. The alimentary hyperglycemia test revealed: fasting, 120 mg. per hundred c.c. of blood; one hour after 100 gm. of glucose, 241 mg. per hundred c.c. of blood. 2 hours, 124 mg. per hundred c.c. of blood.

August 15, the basal metabolism was —29 per cent. The patient was put on 1 grain of thyroid extract, three times a day, at the beginning of the treatment. The basal metabolism eight days later, August 23, was still —30 per cent.; August 27, it was —11.3 per cent.; September 3, normal, and September 10, —11 per cent. September 16 the tonsils were enucleated, and found markedly infected. September 25 the basal metabolism was +11.9 per cent.

This patient was referred for an opinion as to the advisability of a thyroidectomy which had been advised. She was told that the removal of the thyroid would probably have no influence on her general health, and she was placed on thyroid extract, as indicated above. The tonsillar infection was thought to have been an important factor in the case, so the tonsils

were removed. It illustrates the prompt effect of thyroid extract on basal metabolism which, together with the removal of the tonsillar infection, produced a marked improvement in the clinical condition of the patient. It will be noted that the basal metabolism dropped to — 11 per cent. after having reached the normal level, because the thyroid extract had been discontinued at that time. The alimentary hyperglycemia in this case is very interesting. The fasting blood sugar was somewhat high, and following the 100 gm. of glucose there was a very marked hyperglycemia, which illustrates the unreliability of alimentary hyperglycemia as a test for thyrotoxicosis. As stated elsewhere,⁵ alimentary hyperglycemia is due to a variety of other causes aside from thyrotoxicosis, although present in practically every case of the last named condition, but occasionally present, as in this case, in hypothyroidism.

CASE 2.—Hypothyroidism, with latent syphilis and old healed tuberculosis.—History.—Mrs. X., aged 36, had had boils, headaches, general weakness, and abdominal distress, particularly after riding or walking, for a period of six years. The trouble began with an indefinite ache in the neck. The patient noticed also pustules on the head. She felt weak and sick at that time. Soon boils appeared all over the body, continuing for about six months, after which they were limited to the scalp and the right side of the face and neck. The treatment given was unsuccessful. On forced feeding the patient gained 45 pounds, and was free from boils for one and one-half months. Then they recurred and have persisted. Dull, sore, "gnawing" feeling across the epigastrium, having no relation to meals, came on with boils. Usually there was but one boil at a time, associated with small sores on the scalp. The patient had nausea most of the time and felt numb and weak. Abdominal distress had been aggravated since the marked increase in weight. She had frequent headaches. She also had nightmares, and was very nervous. There were no menstrual disturbances.

Physical Examination.—The blood pressure was 120 systolic and 80 diastolic; the pulse was from 85 to 100 and regular. There was diffuse tenderness over the left half of the abdomen, and more or less discomfort in the region of the appendix on deep pressure. A roentgenogram disclosed a stationary tuberculous process in the lungs, without pleural involvement. There was cecal stasis with a typical picture of spastic colitis in the transverse colon, and ulcerative colitis from the splenic flexure downward. The urine was negative. Blood count revealed: hemoglobin, 85 per cent.; red blood cells, 5,810,000; white blood cells, 8,600; polymorphonuclear neutrophils, 51 per cent.; small lymphocytes, 43 per cent.; large lymphocytes, 2 per cent.; transitional cells, 1 per cent., and eosinophils, 3 per cent. The Wassermann reaction was + + +.

Blood sugar, fasting, was 81 mg. per hundred c.c. of blood; urine sugar was 0; one hour after 100 gm. of glucose, 142 mg. per hundred c.c. of blood; urine sugar, + +; two hours after 100 gm. of glucose, 88 mg. per hundred c.c. of blood; urine sugar, +.

A test meal revealed: one hour, free hydrochloric acid, 8; total, 22; one and one-half hours, free hydrochloric acid, 10; total, 25.

The stool was negative.

Because of the tachycardia and nervousness, a basal metabolism determination was made, showing an increase of 53.4 per cent. We have, therefore, to deal in this case with an old tuberculous infection, together with a latent syphilitic infection, probably hereditary, and a moderately severe grade of thyrotoxicosis. The rational treatment of the case is thus clearly indicated, the basal metabolism determination furnishing the necessary proof of overaction of the thyroid gland.

CASE 3.—Hypothyroidism.—History.—Mr. A., aged 41, who complained of "liver trouble," had had erysipelas at the age of 3, and used to have attacks of headache associated with "torpid liver." About ten years before he began to notice constipation. He had attacks of nausea and vomiting every few weeks, gradually becoming worse. He was unable to do any work. He had constipation, with vague gastro-intestinal symptoms.

Physical Examination.—The pulse was 68; the blood pressure, 125 systolic and 95 diastolic. The urine was negative. Blood examination revealed: hemoglobin, 80 per cent.; red blood cells, 5,690,000; white blood cells, 8,200; polymorphonuclear neutrophils, 40 per cent.; small lymphocytes, 40 per cent.; large lymphocytes, 16 per cent.; transitional cells, 1 per cent., and eosinophils, 3 per cent. The Wassermann test was negative.

The alimentary hyperglycemia test revealed: fasting 61 mg. per hundred c.c. of blood; urine sugar, negative; one hour after 100 gm. of glucose, 123 mg. per hundred c.c. of blood; urine sugar, + + +; two hours after 100 gm. of glucose, 115 mg. per hundred c.c. of blood; urine sugar, + +.

Roentgen-ray examination of the gastro-intestinal tract was negative.

A test meal revealed: one hour, hydrochloric acid, 72; total, 88; one and one-half hours, hydrochloric acid, 41; total, 61.

The stool showed many fatty acid needles and crystals, but was otherwise negative.

Aug. 6, 1919, the basal metabolism was — 11.3 per cent. The patient was given thyroid extract, one-fourth grain, three times a day.

August 26, the basal metabolism was + 20.1 per cent. Thyroid extract was stopped.

October 4, the basal metabolism was + 81.3 per cent. On his own initiative he had taken 3-grain doses of thyroid extract three times a day for some time. He was told to stop all thyroid.

October 10, the basal metabolism was + 32.5 per cent.

The clinical improvement occurring in this case was very marked. The patient had been unable to work for a year, and while neither the basal metabolism nor the pulse rate indicated any serious deficiency in thyroid secretion, I decided to make a clinical test. Aside from the clinical improvement that occurred, the most interesting feature of the case was the fluctuation of the basal metabolism in response to thyroid extract, reaching a point as high as + 81.3 per cent. at one time. This occurred without any of the usual symptoms of "exophthalmic goiter," though the basal metabolism test placed it within the group of severe cases. This is explained by the very transient duration of the increased metabolism, which produces the characteristic symptoms only after a considerable period of time. The patient had some slight headache at the time when the basal metabolism reached its highest point, and was perhaps rather nervous. It should be remembered that the patient on his own initiative had taken 3 grain doses of thyroid extract for some time, which accounted for the rather extraordinary rise in basal metabolism. It will be noted that it dropped to + 32.5 per cent. within twenty-four days after the medication had been stopped. The marked clinical improvement in this case following thyroid medication, with very slight manifestations of hypothyroidism, seems to me to be a suggestive and interesting therapeutic observation. This patient has resumed his usual vocation with apparently normal health and nutrition.

CASE 4.—Tuberculosis clinically simulating hyperthyroidism.

—History.—Miss R., aged 24, had headache, severe and constant, during waking hours, with general weakness. She had an acute attack of "influenza" Feb. 3, 1919, and was in bed ten days with nausea and vomiting, but with no fever. She had headache, which had continued since. The blood was examined in April, and the Wassermann reaction reported

5. McCaskey, G. W.: The Differential Diagnosis of Hyperthyroidism by Basal Metabolism and Alimentary Hyperglycemia, New York M. J. 110: 607 (Oct. 11) 1919.

positive. She had headache "all over the head," worse in the morning. There was throbbing all over the body at times.

Physical Examination.—The pulse was 100 to 115, the systolic blood pressure, 145, and the diastolic, 90. The temperature was 98.8. There was a definite enlargement of the thyroid, more of the left and middle lobes. There was tremor, both fine and coarse. The heart was rapid; there were no bruits; rhythm was normal; the left border of the heart was 1 cm. to the left of the nipple. Examination of the lungs disclosed impaired resonance and diminished breath sounds over the right apex. The basal metabolism was +10 per cent. A roentgenogram disclosed evidence of early pulmonary tuberculosis. The urine was negative.

Blood examination revealed: hemoglobin, 70 per cent.; white blood cells, 9,800; polymorphonuclear neutrophils, 51 per cent.; small lymphocytes, 20 per cent.; large lymphocytes, 25 per cent.; transitional cells, 2 per cent., and eosinophils, 2 per cent. Blood sugar, fasting, was 97 mg. per hundred c.c. of blood; one hour after 100 gm. of glucose, 152 mg. per hundred c.c. of blood; two hours after 100 gm. of glucose, 134 mg. per hundred c.c. of blood. The Wassermann test was negative, on several examinations. The tuberculosis fixation test was ++.

The stool was negative. The sputum was scant and mucopurulent; streptococci, ++; staphylococci, +; diplococci, +; influenza, +; pus cells, but no tubercle bacilli.

August 1, the patient was given 2 mg. of old tuberculin hypodermically, with no reaction; August 3, 5 mg. with no reaction; August 6, 8 mg. with a temperature of 101+. The patient felt quite sick during the night; there was a definite general and local reaction.

The weight was 93 pounds, 10 pounds below normal.

In this case there were several of the most important symptoms of thyrotoxicosis, namely, a well marked tachycardia of 100 to 115, and definite fine tremor, together with moderate enlargement of the thyroid gland. There were also general debility, loss of weight, and moderate elevation of blood pressure, with the throbbing indicative of vasomotor disturbance, all of which fit in very well with the theory of thyroid intoxication. The temperature recorded for more than a week showed no elevation. Stereoscopic plates of the lungs revealed lesions which were evidently tuberculous. The physical signs, while not very definite, indicated a lesion, either recent or old, at the right apex. There was some expectoration, showing a mixed infection, as stated above, but no tubercle bacilli were found by the antiformin method. While the case was one in which there was fairly strong suspicion of a chronic infection, yet it was one also in which thyroid intoxication might very easily have played at least a coordinate rôle. This was ruled out by the basal metabolism determination, which was strictly within the normal range, although at the high limit. In such a case one must keep in mind the clinical fact of considerable fluctuation in the metabolic rate in cases of hyperthyroidism of any grade of severity. A single observation of this sort, therefore, must be interpreted with caution, and has the same value as any other single laboratory observation in regard to a fluctuating pathologic condition. In this respect it is probably on a par with a mild positive Wassermann reaction, which is frequently inconstant, or the occurrence of albuminuria or glycosuria. On the other hand, a definite tuberculin reaction, both local and general, together with corroborative roentgen-ray findings, a positive tuberculosis complement fixation test, and suggestive physical findings, seemed to justify the working diagnosis of a tuberculous infection as the principal factor in the case.

CASE 5.—Hyperthyroidism; psoriasis; perverted carbohydrate metabolism.—*History.*—Mrs. S., aged 46, was operated on two years before for disease of the appendix and ovaries.

She developed blood poison, for which she was given serum. This caused a breaking out on the left foot and left side of the body. Rash came on over the whole body, lasted twenty-four hours and then disappeared. For months afterward she was troubled with small pus collections under the nails of both hands. Lesions of the left arm appeared fifteen months before I saw her and had persisted. Similar spots on the left foot dried up but never healed. They burned, but did not itch. The initial lesions were elevated, indurated patches, that soon turned to "blood blisters," and finally the patient picked them off. She stated that her temperature had not been under 100 for many months. She had occasional headache, some vertigo and dyspnea.

Physical Examination.—Sept. 10, 1919, the pulse was 96; blood pressure, systolic, 140; diastolic, 90; temperature, 100.2. There was a definite fine tremor of the hands. There was a symmetrical enlargement of the thyroid; the right lobe was quite palpable and hard. The cervical glands on the right side were palpable and tender. There was an enlarged epitrochlear on the left. There were no bruits or arrhythmia. There was definite edema of the ankles and legs, and general tenderness of the lower abdomen. Skin lesions, typical patches of psoriasis, were found on the left arm and left leg. Roentgen-ray examination of the heart and lungs was negative. The urine was negative. The teeth and tonsils were negative. Phenolsulphonphthalein: 41 + 14 = 55. The blood count Wassermann test and tuberculosis complement fixation were negative.

Blood sugar, fasting, was 168 mg. per hundred c.c. of blood; one hour after 100 gm. of glucose, 192 mg. per hundred c.c. of blood. The nonprotein nitrogen was 27.12 mg. per hundred c.c. of blood. After one week on a carbohydrate free diet, during which the blood sugar slowly dropped, the fasting blood sugar was 148 mg. per hundred c.c. of blood. The same diet was continued twelve days longer. The fasting blood sugar dropped to 86 mg. per hundred c.c. of blood, and continued so for a month, during which time the patient was under rather strict starch restriction (about 50 gm. a day). The basal metabolism was: September 12, +41.5 per cent.; September 16, +52 per cent.; September 20, +49 per cent.

This case presents several interesting features aside from the moderately severe thyrotoxicosis demonstrated by several basal metabolism determinations. The hyperthyroidism itself may easily have been the result of the sepsis, residual evidence of which was found in a suppurating process in the left foot. The fasting blood sugar values are among the highest I have seen aside from cases of diabetes. It is of special interest to note that the hyperglycemia following 100 gm. of glucose amounted to an increase of only 24 mg., or about 14 per cent. of the fasting blood sugar value. The fasting hyperglycemia is not, in my opinion, even suggestive of thyrotoxicosis. It is reasonable to assume that the disturbances of carbohydrate metabolism indicated by a high fasting blood sugar content played an important rôle in the general pathology of the case, including the psoriasis, which, it may be added, improved remarkably on the regimen of starch restriction.

The thyrotoxicosis, whatever may have been its origin, probably played a considerable part in the general syndrome, and could have been recognized only by the basal metabolism determinations. Diabetes mellitus, which might have been suggested by the high fasting blood sugar content, was improbable because of the low blood lipid content.

CASE 6.—Hypothyroidism of puberty.—*History.*—Miss P., aged 16, had choking sensations in the throat. About eight or nine months before the family noticed that she began to gain rapidly in weight. Symptoms began about six months before, and had been getting worse. For the past three or four weeks she had become nauseated at from 10 to 10:30 a. m., being relieved by eating lunch. The menses were normal.

Physical Examination.—The pulse was from 60 to 80. Roentgen-ray examination was negative. The urine was negative. The blood count was normal. The Wassermann test was + +. A test meal revealed: one hour, free hydrochloric acid, 32 degrees; total, 56; two hours, free hydrochloric acid, 20; total, 34.

December 24, the basal metabolism was —15 per cent.

The patient was given thyroid extract, one-eighth grain twice daily, which was followed by rapid improvement.

This case apparently belongs in the group described by Nobecourt⁶ as "hypothyroidea of puberty," which he defines as a minor degree of thyroid insufficiency, a condition which he says is frequently encountered.

The positive Wassermann reaction must not, of course, be overlooked, and as a matter of fact this patient is one of an entire family suffering from various grades of hereditary syphilis. Of course, proper treatment is being given for this trouble.

CASE 7.—Hyperthyroidism, with chronic hypertension.—**History.**—Mr. K., aged 43, complained of nocturnal asthmatic attacks. He had had an acute illness, diagnosed as pneumonia, one month before. One year before, his health began to fail. He began to have some headache, and to lose weight. He had lost 30 pounds during the last year. For the last two years, and probably for the last four years, he had had high blood pressure, ranging from 170 to 200, but he had been getting along fairly well until his acute illness one month before. The trouble began suddenly while he felt in good health. One evening he had a sensation of difficult breathing, with wheezing in the chest, which got so bad that medical aid had to be called. His physician found him with distressing asthmatic dyspnea, and this had recurred every night, becoming very severe at times.

Physical Examination.—The pulse was 135, and regular. The systolic blood pressure ranged from 185 to 200, the diastolic from 130 to 145, indicating rather low pulse pressure. A systolic murmur was heard at the apex. There was an area of dulness over the manubrium. The urine showed some hyaline and granular casts, but the excretion of fluid and solids was within normal range. The blood was normal; the Wassermann test, negative.

June 23, 1919, the blood sugar, fasting, was 0.104; August 7, 0.121; one hour after 100 gm. of glucose, 0.233; two hours after 100 gm. of glucose, 0.140.

Roentgen-ray examination revealed definite dilatation of aortic arch, and enormous enlargement of the heart.

June 3, six days after the first examination, the basal metabolism was +50 per cent.; July 3, +70 per cent.; August 5, +97 per cent. There was a distinct gallop rhythm.

The patient died, October 13.

This case is one of extraordinary scientific and clinical interest. Under rest and varied drug treatment the dyspneic attacks disappeared and the patient improved clinically in every respect. It will be noted that the basal metabolism at the outset indicated a moderate grade of thyrotoxicosis, which it was thought would yield under treatment. No goiter could be detected by us or by the clinicians at the Mayo Clinic, where the patient went later for an examination. He had, however, a very short, thick neck, and a goiter of considerable size might have escaped detection. The subsequent marked increase in basal metabolism is thus best explained by increasing thyroid toxicity. The case was such a typical one of chronic hypertensive cardiovascular disease that the thyroid factor would be pushed entirely into the background unless forced to the front by basal metabolism determinations. The etiologic relationship of the thyrotoxicosis to the cardiovascular disease could not under the circumstances have been determined, but a careful study of

the case suggests, on the one hand, the possibility just indicated and, on the other hand, the desirability of carefully studying the basal metabolism in chronic hypertensive cases to determine the possible evolution of thyrotoxicosis.

CASE 8.—Hyperthyroidism, syphilophobia.—**History.**—Mr. S., aged 31, complained of being nervous and restless, and was always tired in the morning on arising. He had been "doctoring" for the past seven or eight years. He had had some palpitation and dyspnea, and was fully convinced that he had syphilis.

Physical Examination.—This was negative, except for fine tremor. Repeated Wassermann tests (four) were negative. The blood sugar, fasting, was 0.079; it was 0.152 one hour after 100 gm. of glucose, and 0.162 two hours after 100 gm. of glucose. The basal metabolism was +41 per cent.

In this case the determination of the basal metabolism converted a syphilophobic patient into a thyrotoxic one, from the standpoint of diagnosis.

COMMENT

I had hoped to present a larger number of cases, with more abbreviated outline. It seemed advisable, however, to make the case records so complete that the diagnostic bearings of the basal metabolism "settings" would be reasonably clear, even though this made it necessary to omit other interesting cases. There are many aspects of the cases presented which could, I think, be further discussed with profit, but this is also precluded by the length of the paper. So far as I am concerned, this procedure has passed the experimental stage and has been assigned its place in my diagnostic armamentarium by the side of the roentgen ray, the electrocardiograph, serology, colorimetry, clinical chemistry, etc., to be used as occasion requires. While its precise limitations and scope will, of course, be more clearly defined with larger experience, and especially with a fuller knowledge of the endocrinopathies, the attainment of which will be greatly stimulated by its use, the information which it gives in certain cases appears to me indispensable, and cannot be otherwise accurately obtained.

409 West Main Street.

THE TREATMENT OF BRONCHIAL ASTHMA

MARK J. GOTTLIEB, M.D.

Director, Hay-Fever and Asthma Clinic, University and Bellevue
Medical College

NEW YORK

The treatment of bronchial asthma is so much dependent on its etiology and a differentiation from other conditions which have similar symptoms, that it is mandatory that a short sketch of these necessary facts be presented before I enter on the main subject of this paper.

Bronchial asthma may be due to anaphylactic or reflex phenomena. It must be distinguished from asthmatic bronchitis, dyspnea due to cardiac decompensation, uremia, and obstructive dyspnea from inflammatory tissue, tumors or enlarged glands or organs in the lumen of the tracheobronchial tree or pressing on the outside of it. A proper physical examination, roentgenoscopy, urine and blood investigation and endoscopy will definitely exclude all the conditions mentioned except asthmatic bronchitis. The last can be excluded by the fact that it is not dependent on

6. Nobecourt, P.: *Le monde méd.*, November, 1919, p. 257.

anaphylaxis for its symptoms but on definite pathologic changes in the bronchial and peribronchial tissues, which may or may not be readily demonstrated by a roentgenogram.

These items must be determined before one can treat a case of asthma with hope of success:

1. Examination of the nose, throat and teeth, and roentgen-ray examination of the head to determine the presence or absence of pituitary enlargement, and disease in the alveolar processes of the jaws.

2. Search in other parts of the body for infected areas that may be possible sources of reflex irritation or absorption of toxic material, such as may occur from a diseased appendix, gallbladder, prostate, ovary, etc.

3. Bacteriology of the nasal discharges, pus from the tonsils and tooth sockets, bronchial secretions and stool. The suggestion for examining the stool bacteriologically may be open to criticism. I have had one case of colon bacillus anaphylaxis, and several other physicians within my acquaintance have seen similar cases. Furthermore, very often stools are encountered wherein colon bacilli have been partially or even completely replaced by other organisms, such as diphtheroids, unidentified gram-positive cocci, or pneumococci. Stools displaying these bacterial flora are an expression of an intestinal disturbance of bacterial origin which may or may not have a bearing on the bronchial asthma, and it would be unwise to overlook them. Suspensions of the individual bacteria isolated from the various secretions and discharges should be prepared for the purpose of making skin tests.

4. Skin tests with the antigenous bacteria as well as with stock bacterial proteins, epidermal and food proteins, and pollen. A patient has recently come to my notice who was found sensitive to the bacteria isolated from the nasopharynx, but not to the proteins of similar stock organisms. This has been found in other instances, but less strikingly, and is suggestive of a difference in the protein character in different strains of the same organism. Unless a patient is an infant and partaking of only a few foods, we deem it almost indispensable that the patient be tested with all available food proteins irrespective of the age of onset of the disease; for it has been found by us that a patient may be anaphylactic to certain proteins without exhibiting symptoms, and through some unknown reason develop asthma concomitant with or after some infectious disease, such as chronic ethmoiditis.

TREATMENT

Preventive.—In certain very definite instances, infants have been found to be anaphylactic to human milk from birth. Such a condition surely could not have been prevented, and is very unfortunate; however, the simple change from human milk to that of some other species, as cow's milk, will be followed by a complete restoration to the normal. Through some peculiar freak of nature, a child may show evidences of sensitiveness to cow's milk when it is fed such on the first occasion. In this instance the substitution of condensed or dried milks will, in the majority of instances, overcome what at first seems to be an unsurmountable difficulty. When a child is fed an article of diet for the first time, especially when there is a family history of asthma, urticaria, eczema, hay-fever, etc., it should be continued repeatedly and at frequent intervals and not sporadically; for in this way any anaphylaxis which a child might develop by occasionally feeding this particular food will be mitigated or obviated. Bacterial anaphylaxis is a demonstrable fact. It occurs as the result of intermittent absorption of the proteins of dead bacteria from infected areas. For this reason, and because the presence of an infection is a constant source of danger to the patient's health and life, all infected foci should be eradicated as soon as they are discovered. This particularly applies to infected nasal accessory sinuses, and infected tonsils and tooth

sockets, for these areas are most commonly infected and form the basis for innumerable ills besides bacterial sensitiveness.

Climatic.—Only in cases of asthma due to pollen is climatic change of any value, and then it is important to select that locality in which the particular offending plant does not grow. In the vicinity of New York, Fisher's Island, Block Island, Fire Island and Beach Haven are particularly good, except when there is a breeze blowing from the land. More distant localities are of decided benefit, such as the higher levels of the Rocky Mountains, White Mountains and Adirondacks. It is utter folly for one suffering with asthma due to food or epidermal proteins to expect relief by changing climate, because the same conditions will prevail in the new locality as in the old. After a proper diagnosis has been made and suitable treatment instituted, a change of scene and air would be of inestimable value.

Specific.—Generally speaking, it must be said that if a patient is anaphylactic to any one food, that article of diet may be eliminated and the patient recover if there is not a complicating bronchitis, in which instance suitable bacterial vaccine therapy must be given. However, most of the cases cannot be included in this class for the simple reason that patients usually suffer from sensitiveness to more than one food, and in addition may have epidermal, pollen or bacterial anaphylaxis or a combination of all of them. Most foods, however, may easily be eliminated from the diet except milk, eggs and meat. In our experience, patients are not usually sensitive to casein but are sensitive to lactalbumin. By boiling the milk, the lactalbumin becomes coagulated and rises to the surface as a scum and then can be removed. Milk treated in this way can be taken with impunity. In the case of eggs and meats, one of two methods may be employed to desensitize the individual. One of these is the gradual feeding of increasing amounts of egg or meat, beginning with a very small dose. The threshold of reaction must be determined before the treatment is instituted. This may be accomplished by either determining the largest amount of these foods that can be taken by mouth without causing symptoms or by means of skin reactions, following the same technic as described in the treatment of pollen anaphylaxis. The other method is the gradual increase of doses of egg or meat given subcutaneously. Patients sensitive to potatoes may eat them baked, but not boiled or fried. Well toasted wheat bread and puffed wheat, but wheat in no other form, may be partaken. It has been my experience and also that of others working in this field that occasionally a patient may not be sensitive to whole wheat but be anaphylactic to one or more of the individual proteins in wheat. For this reason it is essential that patients be tested with all of the five proteins isolated from wheat. I have observed that when a patient abstains from an article of food for some time, the skin reaction shows less sensitiveness, or no reaction is obtained. Under these circumstances it might be well to have the patient again partake of this food, as he or she may no longer have symptoms from it.

The treatment of bronchial asthmatics who are sensitive to epidermal proteins is very satisfactory, and it is in this class of cases that we procure our most striking results. Patients suffering from anaphylaxis due to cat hair, dog hair, mouse hair, chicken feathers, goose feathers and the feathers of pet birds, such as canaries and parrots, have no symptoms when they are removed from contact with these. When occupation

demands that a person be constantly in contact with the particular epidermal protein that is causing his asthma, such as in the case of furriers and cattle dealers, one of two things may be done; either the patient must change his occupation or be immunized against the particular offending substance; but, in my opinion, it would be necessary for him to discontinue working in that particular field while undergoing treatment. Patients suffering with horse dandruff anaphylaxis, if not very sensitive to horse dandruff, may be comparatively free from symptoms by avoiding contact with horses, or, if they reside near a stable, by changing their residence. For those patients who are sensitive to horse dandruff, in dilutions of the protein weaker than 1:500, desensitization treatment gives wonderful results, the patient usually showing improvement after a few treatments. It has been my experience that the effects of desensitization in horse dandruff cases is not permanent and has to be repeated from time to time. However, fewer treatments are necessary than in the first instance. The same rules as regards the determination of dosage are to be applied here as in the case of pollen anaphylaxis.

Patients may be sensitive to bacterial proteins alone or to other substances besides. Some patients having uncomplicated bronchial asthma show a very decided sensitiveness to certain bacteria. If the bronchial asthma is complicated by chronic bronchitis, the patient may or may not be sensitive to the predominant organism found in the sputum. When the bronchial asthma is complicated by chronic bronchitis, and there is no evidence that the bacteria found in the sputum are producing the asthmatic symptoms by virtue of sensitization, vaccines made from the organisms found should be of inestimable value when combined with the other measures for treating this disease. In some instances, it may be necessary to give three courses of hypodermic treatment at the same time; for instance, when a patient is suffering from chronic bronchitis and an important food and epidermal protein anaphylaxis. If the patient is sensitive to any of the bacteria found in the various discharges or secretions, it is very important not to overdose the patient with the vaccines made from these organisms. It has been my experience that patients suffering with bacterial anaphylaxis, and who are receiving vaccines made from the offending bacteria, do not as a rule exhibit local swelling, redness and pain where the injection is given, but suffer certain general symptoms which are akin to the milder or severer forms of anaphylaxis. For instance, a patient who is under my care at present has had an attack of nausea one-half hour after each injection, and in one instance vomited, six or seven hours later had a chill followed by fever, and a typical severe attack of asthma supervened without there being the slightest evidence of local reaction. It is extremely important, therefore, that the initial dose of bacteria should not be more than twenty million, and not increased more than twenty million each time and at not a shorter interval than four days.

In case that no alleviation from symptoms occurs from subcutaneous vaccine therapy, intravenous injections of vaccine may be tried. When bacterial vaccines are being used and the patient is not sensitive to these organisms, an initial dose of not more than twenty million bacteria may be given intravenously. If, however, the patient is sensitive to the bacteria contained in the vaccine, the initial dose intravenously should not be more than one quarter of that amount. Intra-

venous vaccine therapy is usually followed by a chill and rise of temperature, which may come on at any time between three quarters of an hour and eight hours after the exhibition of the vaccine. Such treatment as this should not be repeated more often than once weekly, and should be preceded in each instance by a urine examination with the idea in mind of demonstrating the presence or absence of red blood cells and other evidence of kidney irritation. Should this be present, the treatment must be postponed until such time as the urine is found to be normal again. A subcutaneous treatment may be sandwiched in between two intravenous treatments. If the patient receives no relief from the vaccine treatment given, it may be that the proper organism is not incorporated in the vaccine, and in that instance it is necessary to take another culture of the patient's secretions and discharges. Some patients require more than one series of vaccine treatments, and they usually do much better with the second and third series than they did with the first.

A large percentage of patients suffering from hay-fever become asthmatic during the hay-fever season. As a rule, asthma occurs only during the latter part of the hay-fever season, the reason for this being that the nose is obstructed because of the hay-fever, and the patient is compelled to breathe with his mouth open. Under these circumstances, pollen-laden air is inspired directly into the bronchial tubes without having the protective action of first passing through the nose. As a result, the pollen causes the same swelling to occur in the bronchial tubes as is present in the nose, thus producing an attack of true bronchial asthma. Because of mechanical nasal obstruction or extreme sensitiveness of the bronchial mucous membrane, some patients become asthmatic at the outset of the hay-fever season, and their bronchial symptoms in this instance overshadow the nasal and eye symptoms with which hay-fever patients ordinarily suffer. Having seen a patient affected with asthma of the aforementioned type, one can readily appreciate the suffering which these patients undergo. The symptoms usually last six weeks or more, and the patient is constantly bedridden. Nothing in the way of relief can be expected from specific treatment under these conditions. It is without reason to add to the pabulum of pollen protein by injecting pollen extracts into a person who is saturated with these and constantly absorbing more through his respiratory mucous membranes. The only logical and reasonable thing to do under these circumstances is to make every effort to prevent the patient from further contact with pollen. This can be accomplished by screening the windows with wet cheesecloth and hanging a moistened sheet over the door. If possible, it is wise to remove the patient to a room on the top floor of some very high building, such as a hotel. The room should have an eastern exposure, and the windows and doors should be protected according to the foregoing suggestion.

In about 50 per cent. of the cases of hay-fever asthma, the attack may be prevented or made so mild that the patient will be comfortable throughout the hay-fever season by prophylactic specific treatment. In New York, most of the spring cases of hay-fever are due to sweet vernal grass, timothy, Kentucky June grass, redtop, and orchard grass. In the fall, as far as my experience has gone, the vast majority are due to ragweed. The other pollens, such as tag alder, sheep sorrel, daisy and goldenrod, play an unimportant rôle. It is absolutely essential that the amount of sensitive-

ness be established by skin tests before treatment is undertaken. This is accomplished by applying the various dilutions of the pollen or pollens to which the patient is sensitive to small scratch marks made on any of the flexor or internal surfaces of the extremities. The dilution next higher to the one that gives a reaction is the dilution with which treatment may be begun. For instance, the patient is tested with dilutions of ragweed extract of 1:100, 1:500, 1:1,000, 1:5,000, 1:10,000, 1:50,000 and 1:100,000. If the patient reacts to all the dilutions up to and including 1:10,000, the dilution of 1:50,000 is that which should be used with which to begin treatment. The initial injection should be 0.2 c.c. of this dilution, and the dosage should be increased by 0.2 c.c. each succeeding time until 1 c.c. of this dilution is given. Then 0.2 c.c. of the 1:10,000 dilution should be injected, and so on as before.

If redness, swelling and itching occur at the site of the injection, it is wise either to repeat that dose at the next treatment or even to diminish it if the action is very severe. When the treatment is begun, as is usually the case, about six weeks before the known onset of the attack, the interval of treatment should not be less than four days. When it is possible, we are now giving weekly injections throughout the year, and our results have been far better than when the prophylactic treatment has been of short duration, just preceding the hay-fever season. This plan is being carried out in the hay-fever and asthma clinic at New York University and Bellevue Medical College. When the stronger dilutions of pollen extract are used, such as 1:500 and 1:100, a great deal of caution must be exercised in increasing the dose, because even a slight increase may precipitate an attack of anaphylaxis; and I would warn those who arrive at these dilutions that the increase in dosage should not at any time be greater than 0.02 c.c.

Drug.—During an attack of bronchial asthma, certain drugs may be used to alleviate the patient's suffering. The solution of epinephrin (adrenalin) chlorid, 1:1,000, when given hypodermically, has the effect of overcoming the spasmodic constriction of the bronchial tubes, and thus stops the paroxysm or ameliorates the symptoms. The effects of this drug begin to make themselves manifest within fifteen minutes, and last anywhere from one half to two hours. For this reason it is necessary to administer repeated doses while the attack, which may last for weeks, is in progress. The patient gradually becomes accustomed to repeated doses of epinephrin, so that the amount given has to be increased from time to time, and finally, the patient develops a complete tolerance to the drug and no more relief is obtained from its administration. The constant exhibition of this drug is not unattended by baneful after-effects; its immediate action of precipitately raising the blood pressure must necessarily have a damaging influence on a heart even in the healthiest condition. Besides this, its constant use is known to produce a sclerosis of the larger arteries. Epinephrin should never be given intravenously, or while the patient is in the physician's office, as I have seen very harmful effects from such practice. Recently Dr. Hugo R. Miller has been using the active epinephrin extract in oil and, when given prepared in this way, he finds that the effect of the drug comes on more gradually and lasts much longer. The adrenalin inhalant, from our experience, is inactive and does not produce the results which Dr. Miller claims for his preparation.

Atropin given subcutaneously or intramuscularly in gradually increasing doses, up to the point of tolerance, and especially when combined with small doses of morphin, will give the patient a great deal of comfort. Potassium iodid, 1 gm. every four hours, helps to render the bronchial secretions less tenacious and more liquid, and thus makes the coughing milder and of shorter duration. Preparations containing the salts of ammonia, especially liquor ammoniae anisatis, disturb the stomach less than potassium iodid, and are just as efficacious. A mixture containing tincture of belladonna, chloral hydrate and syrup of hydriodic acid has been found to make the patient comfortable in the majority of instances. It is surprising how much relief is obtained by inhaling the fumes from a smouldering powder made from nine parts of stramonium leaves and one part of potassium nitrate. This is the basis of most asthma powders on the market. In very severe cases, nothing short of large doses of morphin hypodermically will give the patient the necessary respite and mental rest from the distressing paroxysms. When the bronchitis persists between attacks, nothing is more efficacious to alleviate the cough and sustain and soothe the patient than Thompson's mixture of linseed oil¹ with codein or compound tincture of opium. Applications of cocain and epinephrin directly to the mucous membrane of the bronchial tubes through a bronchoscope during an attack certainly give respite from symptoms; but the duration of the relief is too short to warrant this trying procedure.

NUTRITIONAL EDEMA AND "WAR DROPSY"*

MARIA B. MAVER, M.D.

CHICAGO

Before the recent war, medical literature contained frequent references to the type of edema now recognized as "war edema." With the clinical picture in mind presented by meager reports that have appeared in the American¹ and British scientific journals of recent publication, a somewhat extended study of wars, famines and epidemics of the past has proved fruitful in bringing to light evidence of the prevalence of edema of this type under varying conditions of insufficient and inadequate food. This edema resembles that of renal disease. In mild cases it may be confined to the lower limbs, but in the severe type the edema may extend to all parts of the body. There is no albuminuria. Accompanying this edema there are emaciation, muscular weakness, depression, anemia, and very frequently gastro-intestinal disturbances.

While the term war edema is not found in early medical literature, there is much evidence that the condition known by this term has been of frequent occurrence in the past. In giving a name to this disease, the authors usually express the chief etiologic factor with the most pronounced clinical symptom, so that war edema, prison dropsy, hunger swelling, epidemic dropsy, edema from inadequate food, deficiency edema, edema without albuminuria, and many similar

1. Mixture of linseed oil (Thompson) consists of: dilute hydrocyanic acid, 10 c.c.; oil of wintergreen and oil of cinnamon, of each, 8 c.c.; glycerin, 20 c.c.; simple syrup, 300 c.c.; Irish moss, 15 gm.; linseed oil, 450 c.c., and water, 780 c.c.

terms have been used. In civil practice previous to the war, essential idiopathic or primary edema, salt edema in children, alimentary dropsy, anemic dropsy and edema following gastro-enteritis were some of the more common terms employed.

Prinzing² makes no mention of war edema from the time of the Peloponnesian Wars, from 430 to 425 B.C., to the siege of Port Arthur in 1904. In a large number of these etiologically related conditions, edema appears as a symptom rather than as a specific disease. In the destruction of the French army before Naples in 1528,³ "those soldiers who were not confined to bed in their tents were seen with pallid visages, swollen legs, and bloated bellies, scarcely able to crawl."

Vacher,⁴ writing of the conditions of childhood during the siege of Paris in 1870-1871, finds that the effect of insufficient nourishment showed itself in progressive emaciation, edema of the integument, anemia, and uncontrolled diarrhea, which were characteristic symptoms of the hunger fever which decimated the infant population. Between 1877 and 1880, there broke out in Calcutta a peculiar disease to which the term "epidemic dropsy" was applied.⁵ This disease followed an extensive famine in southern India.⁶ It persisted in epidemic form until 1880. The number of cases increases in each cold season and falls off in each hot season. It has continued to appear in Calcutta sporadically. Neighborhood and family groups continued to be reported until 1915.

Edema of war occurred during the Napoleonic campaigns, the siege of Paris, and in the concentration camps during the Boer War, when it was known as epidemic edema.⁷ Falta⁸ of Vienna mentions that the disease was known in Russia during famines before the war, and that the expression "swollen from hunger" was current in the affected districts. Landa⁹ related that in August, 1915, when the City of Mexico had been the seat of military operations for two or three months, the appearance of numerous cases of edema began to be noted. Starvation edema was reported by Dr. Patterson¹⁰ in 1899 after a season of famine in China. Holst,¹¹ in connection with his researches in ship beriberi and scurvy, furnishes this interesting group of historical data:

Many dropsical cases were observed during the Crimean War when scurvy was prevalent. Dropsy without sore gums occurs every year on board the French fishing vessels off the coast of Newfoundland. During the first part of the nineteenth century dropsy was common in European and American prisons. This prison dropsy is stated in 1847 to have been, besides typhoid fever and consumption, the most prevalent cause of death in forty-one prisons in England, France and North America. In 1857, it caused one-half the deaths in a prison in Breslau.

RECENT REPORTS OF EDEMA IN EUROPE

The first record of war edema in the recent war was made in 1915 by Strauss, who described the "hunger

disease" in Russian Poland and Galicia, where the poor had an insufficient and monotonous dietary, and were exposed to war epidemics. About the same time, in July, 1915, Budzynski and Chelchowski¹² described a series of 110 cases of a peculiar affection occurring among the inhabitants of certain towns in Poland as a result of insufficient and inadequate food caused by the German occupation. The name "hunger swelling" was applied to this disease because its most characteristic feature was the presence of marked edema, recalling that encountered in dropsical beriberi. All the patients suffering from the disease were in a state of semistarvation.

In Germany, war edema first made its appearance in prison camps in July, 1915. Rumper at first considered relapsing fever responsible, but in 1916, when many cases with dysenteric symptoms occurred in prison camps free from relapsing fever Rumper and Knack¹³ regarded dysentery as a predisposing cause. At this time, cases were reported among Russian soldiers at the front. Early in 1917, there were many cases in the civil population and labor battalions in Germany, and in the spring, cases appeared in Austria among civilians, especially workmen, but rarely among the troops. The disease appeared in Vienna with great suddenness. In 1917, marked attention was given in German medical journals to this peculiar disease, which seemed to have become widespread throughout Germany. The first cases noted in Berlin were in January, 1917.

Guillermín and Guyot¹⁴ made personal observations and reported in March, 1919, that insufficient food in Russia, Germany and Austria had caused a specific disease of hunger which was known as hunger edema. These authors described the disease as it occurred among French prisoners of war.

In Poland, the patients were in a state of semistarvation, none having eaten meat for several months and some not since the beginning of the war. The cases occurred almost exclusively among the poorest of the people and the unemployed factory hands, who were without money to buy food at the famine prices. The staple diet of the people consisted of potatoes supplemented by small quantities of soup and bad bread on certain days. The amount of potatoes eaten averaged 5 pounds for each person daily, a dietary which caused diarrhea and eventually led to most of the food's being passed through the gastro-intestinal tract undigested. The causes of the disease, according to the Polish authors Budzynski and Chelchowski, were lack of proper food, especially the absence of fats, and the large amount of bad potatoes consumed. Maase and Zondek,¹⁵ in agreement with other authors, consider the cause of the disease to be underfeeding, resulting especially from the diminished quantity of fats. Another factor suggested was the amount of fluid ingested. Owing to the changed conditions, most of the sufferers had been taking a more watery diet than normally, in the form of soups, turnips, etc., and the occurrence of diarrhea was fairly common. Schiff¹⁶ suggests that this purely war disease has obvious similarities to beriberi and other diseases resulting from a lack of vitamins. Falta says that all of the patients

had been improperly fed for a long time, especially as regards proteins, and the liability to edema, always present in malnutrition, was aggravated by the large quantity of sodium chlorid in the food. He states that persons showing war dropsy had usually been getting from 1,200 to 1,400 calories a day, including only 30 to 50 gm. of protein. But as such degrees of edema do not ordinarily occur in simple starvation, he believes that another factor must be present in these cases, namely, the ingestion of large amounts of fluid and salt in the attempt to sustain life on the thin vegetable soups common in prison camps and in famine districts. Cold, hard work and infectious diseases increase the tendency to edema simply because they increase the deficiency in food calories.

The Swiss authors found that in some regions the conditions of underfeeding were extreme, resembling the great famines of history. The disease was also very frequently found in men who were subject to hard work on a diet of from 800 to 1,200 calories, consisting of 15 per cent. and more of indigestible cellulose, bread containing 97 per cent. potatoes, very little fat, and a ration of 50 gm. of albumin, daily, at the highest. Exposure to cold and hard physical labor were contributing factors in the development of this disease.

Maase and Zondek¹⁵ suggest that the toxic products of protein metabolism may cause damage to the endothelial lining of the blood vessels and so lead to edema. The high residual nitrogen and ammonia values found by them in the urine, blood and edema fluids were considered to be evidence of this hypothesis. Franke and Gottesmann,¹⁷ in their study of the functional efficiency of the kidney in seventeen cases of war edema, found delay in excretion of urea and sodium chlorid in ten patients, and of potassium iodid and lactose in seven. They therefore call war edema a nephritis without albuminuria.

Maliwa,⁷ from investigations of four cases, correlates the stage of polyuria with an excess of sodium chlorid in the blood, and finds that after the polyuria has passed off the blood is deficient in the sodium chlorid content. The change in the osmotic relations of the tissue is the essential factor in the disease, the polyuria and edema, though prominent clinical features, being secondary in importance. To determine the cause of the edema, Knack and Neumann¹⁸ sought to secure its return in convalescents by restricting the diet principally to turnips, and by giving large quantities of water internally. Neither measure separately ever produced the result, but with the restriction of the diet, plus water drinking, the edema rapidly returned in convalescent patients. Lange¹⁹ discusses the causation of a group of cases observed by him in West Prussia, and concludes that an altered permeability of the blood vessels was present, owing to a qualitative alteration in the food, perhaps to the extreme deficiency of calcium. Hulse²⁰ reaches similar conclusions, except that the edema was more frequently found as a sequel to relapsing fever, and in men who had been previously exposed to extreme cold. Recent writers discuss the subject of vitamins and the rôle they play in deficiency diseases, especially those belonging to the beriberic type, but gen-

erally recognize that it is not a well-defined deficiency disease, and in the majority of cases is the result of an inadequacy of diet to supply the nutritional requirements of the body.

The characteristic symptoms found among the inhabitants of certain towns in Poland were edema, debility, muscular weakness, intestinal disorders, mental depression, dimness of vision, disappearance of sexual impulses, and alterations in the blood and urine. With the disappearance of the edema the wasting was evident, the patients sometimes being reduced to mere skin and bones. Maase and Zondek¹⁵ state that there were no noteworthy premonitory symptoms, but suddenly marked edema developed, especially in the lower limbs, with anemia and frequent diarrhea. Among French prisoners, there was great emaciation, the loss of weight being frequently 40 per cent. of the initial weight, anemia, general edema, muscular weakness and nervous exhaustion; and apathy and depression were associated with a "facies pestica." Falta states that prostration, apathy and weakness were almost constant; a feeling of heaviness in the legs, and diminished reflexes were found, but no typical polyneuritic symptoms occurred. The nutritional value of the food was still further diminished by diarrhea and dysentery, which were frequently associated early in the development of the disease.

In cases among the civil population, the edema was generally located in the feet and legs, occasionally in the thighs and trunk. In more than one-half the cases there was some degree of facial swelling; in one-sixth, the hands were swollen, and in one-ninth ascites was present. The face and scrotum were often affected, and in a small number of cases, ascites and hydrothorax occurred. Its features were remarkably uniform: the edema resembled that of renal disease and in mild cases was confined to the lower limbs; but in severe cases it was universal and caused considerable limitation of movement, sometimes interfering with the opening of the eyes. The edematous tissue was soft and elastic; the skin and puncture fluids were pale. In some cases the edema came on gradually, but after severe physical exertion, more rapidly. Following the disappearance of the dropsy, relapses were prone to occur, especially if there was any return to hard work or unsuitable food. The edema sometimes led to bursting of the skin with serous exudation, or so stretched the skin that pink scars like striae gravidarum resulted from it. The swollen extremities felt cold, and were painful when touched. Beyermann²¹ states that twelve cases among the insane suggested scurvy or purpura except for the remarkably slow pulse and the absence of changes in the gums. On the addition of fresh vegetables to the ordinary diet, conditions returned to normal.

The urine was usually pale like water, alkaline, and contained neither sugar nor albumin. The amount of urine passed varied greatly in different cases, but on the whole was increased, sometimes reaching 60 ounces and over when the swelling was disappearing. As soon as the patient was put to bed, a marked diuresis began, and during the stage of recovery the amount of urine passed daily was from 3 to 4 liters. High residual nitrogen and ammonium values were found in the urine, blood and body fluids. Falta found polyuria and frequency of micturition; the urine being clear, of low

specific gravity, and free from albumin and formed elements, except a few hyaline casts. Tonin²² comments on the odd fact that polyuria constantly accompanied the hunger edema in ex-prisoners of war seen at the hospital. As noted by others, this polyuria usually began when the patients were at rest in bed.

Jensen's²³ study of the blood showed from 1.5 to 4 million red corpuscles with a color index greater than one, usually with a leukopenia, in 60 per cent. of the cases there being less than 5,000, with a relative lymphocytosis (from 30 to 55 per cent.). The coagulation time was usually shortened, and the blood proteins were nearly always decreased, generally being from 4 to 6.4 per cent. (normal is from 6.5 to 8.5 per cent.), that is, there was a hydremia with hypo-albuminosis. The freezing point was normal, the residual nitrogen normal or low, uric acid normal, and sugar and calcium usually low, chlorin usually approaching the upper normal figures, although it was occasionally low. Chemical examination of the blood and urine (Knack and Neumann) revealed a diminution in lipoids and in the organic phosphorus content of the blood. The depletion of the tissues in nutritive reserve in war dropsy is shown by Falta's statement that when absolute fasting is studied in these cases there are only from 2 to 3 gm. of nitrogen eliminated per day, as against 10 to 12 gm. of nitrogen excretion during the fasting of normal persons.

There were no cardiac symptoms reported by Maase and Zondek, but other observers found a condition suggestive of a cardiac lesion with failing compensation. Falta states that the slow pulse, from 35 to 40 a minute, characteristic of war edema, is best marked in males. Schiff reports a somewhat higher pulse rate of from 42 to 56. The edema was frequently observed with cardiac symptoms and infections in children, but in adults without these complications.

Hemeralopia frequently preceded the development of the edema. In severe cases, corneal ulcer and xerosis of the conjunctivae were troublesome. Ophthalmologists describe these eye changes as the result of debility and poor nourishment. Nyctalopia, or night blindness, is common in the spring and fall as a symptom of debility. Night blindness seldom occurs as a functional disorder except in cases of general debility, starvation or scurvy. The development of xerophthalmia is now recognized as due to a specific deficiency in fat-soluble vitamins. Maynard²⁴ discussed twenty cases of increased intra-ocular tension found in the course of epidemic dropsy. There was dimness of vision, the cornea was a little steamy, and the pupils were small or moderately dilated. The tension of the eyeball was distinctly increased. Halos, generally rainbow-like, were complained of at one time or another during the attack of dropsy.

Vandervelde and Cantineau²⁵ made observations on 200 patients treated by them in the St. Pierre Hospital at Brussels. Most of these cases were among deported Flemish civilians. There was marked edema of the lower limbs, frequently associated with "grave phlegmons." The general condition was brought about by lack of food and by deplorable hygiene. There were weakness and profound anemia; and dyspnea resulted from the slightest effort. Those deported

were recruited without any medical examination and were forced to do hard physical work. Minor symptoms and complications were common. Among these were: ringing in the ears and dry, painful skin with frequent secondary pyogenic infections; and in one or two instances dark pigmented patches were observed on the face, similar to the pigmentation in Addison's disease. (Noted by the Polish authors.)

In mild cases under the influence of a more generous dietary, recovery took place. The regulation treatment for the condition consisted in a better diet as far as possible and rest in bed until all swelling had disappeared. Knack and Neumann found that recovery always followed rest in bed on ordinary hospital diet and that the restriction of fluids was rarely necessary. Maase and Zondek, by giving three patients 100 gm. of fat daily for a week, were able to cure the disease completely without rest in bed or other remedial measures. The diet should be ample, especially in regard to protein. The lack of resistance to cold is striking, death following relatively slight chilling, so that warmth is an important part of the treatment. The prognosis is good if the patients are kept in bed on a proper diet, but severe cases frequently prove fatal. Postmortem findings are seldom reported. Chronic marasmus with atrophy of the viscera, especially the heart and spleen, fatty degeneration of the liver and kidneys, and in some instances, dysenteric ulcers were found. In three cases Budzynski and Chelchowski found a diminution in the amount of blood, and a reduction in the size of the liver.

REPORTS FROM INDIA, CHINA AND MEXICO

Leaving the recent reports of edema in Europe and turning to the literature of other countries, we find that in many lands similar epidemics of dropsy have resulted from famine. Until the appearance of "epidemic dropsy" in India following the famine in 1876-1877, "swellings" were regarded as a minor symptom, when arising in the course of famine diseases. During this famine the mortality was high, and in eight famine districts nine tenths of the total recorded deaths were caused by famine diseases—dysentery, dropsy, diarrhea and debility.²⁶ Government works and a system of rationing were established for men, women and children unable to earn the daily ration. To test the value of this ration, a system of weighing the people was undertaken. In these tests great caution was found necessary for, it was reported, many of the people who came into the camps appeared to be filling out and fattening, when in reality they were getting dropsical and in a fair way to die. In the nursery of the famine relief camp near Madras, many children were found to be in a dropsical condition, and most of the old people were in the same state. Old men and old women were bloated with dropsy, and others again, many of them in the prime of life, were mere skeletons, the bodies of full grown men weighing only from 58 to 85 pounds at necropsy.

To supply the vast population of southern India with the necessary amount of food for health was the "Hoover problem" of the famine relief agencies. Practically all the grain had to be imported, and transportation facilities were inadequate. It seemed necessary to keep the grain ration, principally rice, as low as possible. Animal foods were scarce. Dr. Cornish, adviser of the government of India on public health

questions, pointed out that effects of insufficient nourishment might not be immediately apparent, and throughout the famine constantly emphasized the importance of the nitrogenous value of the ration, and advocated a ration consistent with age and work, sufficient to replace tissue waste. After this famine, reports began to appear in the *Indian Medical Gazette* of acute dropsy and acute anemic dropsy. In 1881, McLeod²⁷ termed the disease "epidemic dropsy." The "new disease" continued to be the subject of many reports and extensive bacteriologic investigations until 1909-1910. According to bacteriologic phraseology, it appeared endemically and epidemically, and much study was given to a specific organism, with no constant results.

Dr. Greig,²⁸ in his report on epidemic dropsy, states that there is evidence to show that epidemic dropsy is a nutritional disease which is brought about by a one-sided dietary, and that the two severe outbreaks of epidemic dropsy in Calcutta and Bengal, namely, from 1877 to 1879, and from 1907 to 1909, have been correlated with a sustained high price of food grains during this period, and the cessation of these epidemics has synchronized with the fall in prices of food grains. The study of the parasitic origin of disease has somewhat overshadowed the question of the relation of defects of dietary to the causation of disease in the tropics. In one locality, Greig found in 321 houses, with 4,637 inhabitants, 1,581 persons who were dropsical. The persons attacked consumed polished rice, and this was their staple diet. The amount of rice consumed daily varied from 2 to 16 ounces (from 1 to 8 chittaks). When the price of grains rose, the capacity for purchasing additional suitable articles of diet diminished and the diet became dangerously onesided.

The peculiar qualities of rice as a diet were pointed out by McCay²⁹ in his investigations of jail dietaries. Rice is the poorest of all cereals in protein, and when cooked it swells up and absorbs three and one-half times its weight in water. The percentage of starch in rice is high—up to 80 per cent. Rice is deficient in fat. Rice is a bulky diet, 26 ounces of dry rice when cooked measuring about 2,800 c.c. A large carbohydrate diet, by its mere presence in the intestinal canal, hinders the absorption of protein. On account of the fermentation processes that are quickly set up, there is increased peristalsis, and the food is hurried through the small intestine past the area most favorable for absorption. The amount of rice present in the diet influenced in a marked degree the quantity of urine excreted. The rice may have a diuretic action on the kidneys, or water may be formed in the tissues from the constituents of the rice, in addition to the large water intake with the boiled rice itself.

Dr. Patterson³⁰ of Chinkiang, China, described a group of cases of dropsy occurring in dispensary patients after a famine season. The food of these people consisted largely of weeds and wild plant greens. As no literature could be found on the subject, the disease was called "greens dropsy." The only symptom complained of was the swelling. With some medical treatment and money to buy grain, the patients recovered rapidly.

When the City of Mexico had been the seat of military operations for two or three months, Landa³¹ related that many cases of edema in men, women and children began to be noted. Hundreds of cases were found with no albuminuria. As in other famine epidemics, many persons died of actual starvation, while others developed edema cachexia from defective nourishment. The mortality was high, the patients dying in marasmus with heart failure. There was hydremic anemia, hypothermia, slow pulse, reduction of the reflexes, and pain in the muscles. The only food obtainable had been vegetables of the families *Chenopodiaceae* and *Amaranthaceae*, such as beets and spinach.

RELATION OF WAR EDEMA TO DEFICIENCY DISEASES

Frequent reference is made to the similarity between the clinical symptoms found in war edema and those associated with diseases of the beriberi type. Falta states that the wet form of beriberi is the only other deficiency disease in any way resembling war edema. In this group of edematous diseases, as discussed by various authors, are tropical beriberi, ship beriberi and epidemic edema. The polyneuritic symptoms in tropical beriberi have been so constantly emphasized that they have obscured the equally important edematous conditions which form the chief feature in the wet type of the disease. In epidemic edema and ship beriberi, nervous phenomena are rarely present, but edemas of various degrees constitute the major symptom. Infants nursed by beriberic mothers suffer from edema, dyspnea and cyanosis. Authorities agree that this is an infantile beriberi due to some deficiency in the mother's milk. Almost all cases of infantile beriberi are edematous. The pathologic findings observed at necropsy in 219 infants under 1 year of age showed a percentage of 56.6 of infantile beriberi. Vedder and Williams³² regard this edema in infantile beriberi as due to a specific avitaminosis. Vedder³¹ furnished a list of food deficiencies found by the various investigators in beriberi: (1) deficiency in fat (Bremaud and Laurent); (2) nitrogen starvation (Takaki); (3) deficient vegetables combined with an infection (Fales); (4) deficiency in organic phosphorus (Schauman) and (5) deficiency of some unknown substance, not phosphorus (Fraser and Stanton, Chamberlain and Vedder, Shiga and Funk).

It is interesting to contrast with this group the findings by the various authors in war edema. The lack of calcium, fat, phosphorus in the blood, fresh vegetables, proteins and vitamins have each been emphasized in war edema. In addition there was general underfeeding; the diet as a whole was low in caloric value. The food was quantitatively as well as qualitatively deficient. There was semistarvation.

Lind,³² in his early account of scurvy, found dropsy a constantly recurring symptom. Scurbutic persons were found to have edematous swellings at first about the ankles, later extending to the legs and other parts. The face, especially, became pale, swelled and bloated. Long want, improper diet, melancholy and cold are given among the causes. Dr. Cook, in a letter to Lind at this time, finds the term "nervous disorders" universally applied to most chronic and cachectic ailments. The lower people "who live continually on

farines and a gross diet," and among whom these complaints are found, had a universal lassitude, pains which they termed rheumatic, and a breathlessness on exercise. The legs were sometimes swollen and the abdomen almost always tender and tumefied. Professor d'Espine observed these edemas during the siege of Paris as a first stage of scurvy; and Guillermin and Guyot, commenting on similar scorbutic complications, ask if scurvy may not be simply a state more advanced in the evolution of this disease, of which edema is an initial symptom. But the number of deaths occurring without scorbutic symptoms seems to plead for war edema as "une entité morbide." Dropsical patients without sore gums were frequently observed in epidemics of scurvy in Russia during the Crimean War when scurvy was very prevalent.

In pernicious anemia associated with pregnancy, Williams³³ finds anemia, weakness, shortness of breath, and edema of the extremities. A general puffiness affecting the hands and face as well as the legs, without urinary findings, is common in hydremic patients. More than half of all pregnant women, according to DeLee,³⁴ show some edema of the feet, the hands or the face. Often this is an elastic puffiness that does not pit. The cause of this is not known. In reproductive processes throughout nature, growth occurs at the expense of the maternal tissue. The protein materials are chiefly concerned in the growth of the new cells. Miescher³⁵ showed that salmon, after entering the Rhine from the sea, virtually starve. Yet the genital organs of both male and female develop greatly at the expense of the liquefying muscles, which may lose 55 per cent. of their weight (protein) without destruction of the muscle cell.

In war edema and in the etiologically related edemas in deficiency diseases, hydremic anemia is a somewhat frequent symptom. Osler and McCrae,³⁶ in their study of the circulatory disturbances in a group of cases of chlorosis, find dyspnea in 318, palpitation in 254, and edema in 231. "Doubtless it is the occurrence of slight degrees of edema which gives chlorotic patients so plump a look." All the symptoms come on in the course of from three to twelve months. The disease is most common in ill fed and overworked girls.³⁷ A long continued unbalanced diet may play a large part in the process.

Sir Joseph Fayrer³⁸ finds that pernicious anemia in Europe resembles beriberi in the Orient. Bramwell,³⁹ in a table showing the most important symptoms in forty-five cases of pernicious anemia, records twenty-three cases of dropsy, associated with great prostration, weakness and loss of weight. The urine was normal in the majority of cases. This edema was considered as partly due to the watery condition of the blood, and partly to the enfeebled state of the heart. Functional derangements of the stomach and intestine are almost invariably present. A symptom⁴⁰ which is practically never wanting is edema, especially of the legs and

under eyelids, though it is also seen in other places on the body. The swelling is practically never marked, but is very persistent, and is noticeable as one of the earliest symptoms of the disease. Moreover, it readily recurs in patients who show a complete remission. As in other anemias, the edema is possibly due to alterations in the blood vessel walls. A gain in body weight in pernicious anemia when unattended with increase of hemoglobin indicates dilution of the blood and escape of serum into the tissues.

Edema occurring in the course of gastro-intestinal disorders and marasmic conditions in infancy is somewhat infrequent but well recognized by pediatricians. Chapin⁴¹ reports twenty-one cases of general and local edema in which neither the condition of the blood nor that of the urine explains satisfactorily the development of the edema. The clinical conditions in which these edemas are most frequently found are: (1) difficult digestion and malassimilation with gastro-intestinal disturbances and diarrhea; (2) exhaustive conditions, such as prematurity, marasmus, extreme secondary anemias, edema neonatorum, and in long debilitating diseases; (3) occasionally in various constitutional diseases, such as syphilis, tuberculosis, erysipelas, and pertussis, and (4) in angioneurosis of vasomotor origin.

Under the term essential, primary or idiopathic edema, Wagner,⁴² in 1887, records the earliest account of this disease. An epidemic of edema in which thirteen cases occurred in thirty-five babies in which gastro-enteritis was prevalent was thought by De Wolf⁴³ to be of infectious origin. The cases all occurred within a short time in a children's hospital in which the food supply was modified milk alone, or modified milk with the addition of a cereal or a proprietary food.

Potter,⁴⁴ in a group of cases of diarrhea with edema following a diet of barley water with a low percentage of fat and protein, increased the fats and proteins with the disappearance of the edema in a short time. The same author later reports a large group of cases in which he considers the edema a symptom of malnutrition and marasmus. In typical cases these babies had been treated for some time with boiled water, barley water or whey. A slight gain in weight occurred as the edema developed. Potter says that it is not what the babies are being fed that causes the dropsy, but what they are not being fed; also that it is entirely owing to the fact that they are not getting enough proteins in the diet, and this notwithstanding the intestinal disturbances that practically always accompany or precede the edema. It may be that in many of the cases the continuance of the diarrhea itself is due to the deprivations of solids in the food.

Czerny and Keller⁴⁵ use the term "Mehlnährschäden" to describe a condition found in infants fed on a high carbohydrate diet, but lacking in other important foodstuffs. The tendency of the tissues to hold water is increased in carbohydrate feeding. Holt⁴⁶ finds general edema as a symptom in marasmic infants. There is often increase in weight, and the whole body may become waterlogged. The symptoms shown by some

infants that have been fed for a long time on an almost exclusive carbohydrate diet indicate that they suffer from "Mehlnährschäden." The carbohydrate diet is frequently given in the form of proprietary foods and cereal decoctions to overcome diarrhea. Bloch⁴⁷ applies the term carbohydrate dystrophy to a group of cases in which he found xerophthalmia associated with edema resulting from fat deficiency and a carbohydrate diet. Hume⁴⁸ observed thirteen cases in which edema appeared following gastro-enteritis and vomiting. There was no marked error in the diet to throw light on the etiology of the condition. His observations on salt retention in these infants failed to be conclusive, and as there was no evidence of kidney or heart disease, the pathologic condition was sought for in the tissues themselves. The action of toxins, developed in the gastro-intestinal tract, on the supra-renal or capillary cells is suggested as a possible cause of the condition.

Ashby⁴⁹ finds these edemas following gastro-intestinal catarrh which has persisted for weeks. The gastro-intestinal tract is so deranged that poisons absorbed from it reach the systemic circulation and in this way lower the vitality of the endothelium of the blood vessels, causing an increased permeability. Recurrences were common, and these children seemed to do better on food containing a high percentage of proteins with a low percentage of carbohydrates.

In a review of the literature on osmosis and edema in infancy and childhood, Waterman,⁵⁰ as late as 1914, finds uncertainty as to the methods of the production of this edema. In the light of present knowledge, the weight of evidence seems to be in favor of the chlorid retention theory of infantile or essential edema, although the vascular lesions theory has many points in its favor. The etiologic factors considered by this author are: (1) latent or hidden nephritis; (2) chlorid retention which leads to a hydremia and so to an edema, and (3) increased permeability of the capillary walls.

In reviewing these various etiologic factors, there is evidence that the same type of dietetic and pathologic conditions is found in these edemas in infants as those concerned with war edema and the edemas found in the deficiency diseases of the beriberi type.

A general dropsy is a common symptom in hydremic animals. Friedberger and Fröhner,⁵¹ and Hutyra and Marek⁵² describe this condition as it occurs in draft oxen and horses that work in sugar factories and in other cattle from exclusive feeding on distiller's wash. The disease is chiefly caused by feeding on beet root residue, which contains only about 5 per cent. of solid matter with 95 per cent. of water. As the proportion of proteins in the solid matter is only 1 to 10, the residue contains 0.5 per cent. proteins. Consumption of such food combined with hard work results in hydremia. All tissues are infiltrated and the body cavities filled with transudate.

A similar condition of dropsy or "cachexia aquosa" is found in sheep from insufficient pasture and unfavorable climatic conditions, such as wet or cold weather, badly situated grazing lands, and penning the

sheep on wet, cold soil.⁵³ Weakness, emaciation, anemia, depression and exhaustive diarrheas accompany this condition.

EXPERIMENTAL EDEMA

Denton and Kohman⁵⁴ find that dropsy occurs in a large percentage of rats fed on a carrot diet, when the proportion of nitrogen is reduced by the addition of some non-nitrogenous foodstuff, such as fat or starch. Kohman,⁵⁵ in further experimental work, produced edema in a large percentage of rats fed on a diet composed largely of carrots. The addition of fats or fat-soluble vitamin, or water-soluble vitamin, or increase in salt content of the diet had no noticeable effect on the occurrence of edemas, but there was much more marked edema when there was much water in the diet than when the animals were on a dry diet. On the addition of a sufficient amount of an adequate protein to the carrot diet without change in caloric value, no edemas occurred and the animals grew normally. Control experiments showed that the edema was not due to toxic products in the carrots, or to starvation from low caloric intake.

Harden and Zilva⁵⁶ observed edema in one of three monkeys fed on a diet complete in every respect, except that it lacked the fat-soluble "A" factor and was low in fat. Each of these animals received a daily diet of from 250 to 300 gm. of boiled, polished rice, marmite, 10 gm., and salt mixture, 2 gm. (The large amount of rice in this diet may have hindered the absorption of the protein.)²⁹

Extensive experimental work was conducted by Holst and Frölich¹¹ in an endeavor to produce ship beriberi in animals. Abortive cases of scurvy resembling ship beriberi were repeatedly seen in guinea-pigs, but although these authors were unable to produce typical ship beriberi they frequently observed edema.

I have carried out a number of dietetic experiments with dogs, rats and guinea-pigs. These animals have been variously fed on specially prepared breads containing much cornstarch in order to reduce the protein content; also, in the case of the rats and guinea-pigs, diets of beets, turnips, cabbage and potatoes with or without the addition of starch bread or plain bread. It has not been possible to carry out this work to the extent desired to make a complete study of the subject; furthermore, the work of Miss Kohman seems to cover the ground sufficiently well. Therefore no details of this work will be published. To summarize the results it may be said that in a number of animals edema was obtained, and that these cases occurred under such conditions as to agree fully with Miss Kohman's conclusions. That is to say, edema was not observed in animals that received a dry diet even when they were allowed to take such water as wanted. Most of the instances of distinct edema were observed in animals that lived on a diet poor in protein and fats and containing much fluid. For example, no edema was observed in guinea-pigs living on potato and rye bread, or on meal bread or rye bread alone; whereas a few of the guinea-pigs living solely on beets or cabbage showed more or less edema. A few rats fed

solely on a carrot diet also showed edema. In one of these the visible edema disappeared when casein was added to the diet and returned when the animal was again restricted to carrots. This work adds nothing to Miss Kohman's observations, but furnishes merely a certain amount of additional corroboration.

GENERAL CONCLUSIONS

It will be seen that the final conclusions reached by those who have studied war dropsy are in extremely close accord. This condition seems not to be a typical "deficiency disease" in the sense of being the result of a deficiency in one or more specific unknown constituents (vitamins) in the diet. In a broader sense it is, however, a deficiency disease, and is the result of a protracted existence on a diet deficient in total calories, especially in protein. Undoubtedly, a high fluid intake, and possibly a high salt intake, are important accessory features. Hard work and exposure to cold are factors simply in that they increase the caloric deficiency of the food supplied.

It is gratifying to find that the experimental work agrees perfectly with the clinical evidence in establishing that a combination of low calories, low protein and excessive fluid intake will lead to a marked dropsy corresponding to war dropsy in all respects. The importance of specific vitamins seems to be excluded by these experiments.

Undoubtedly, dropsy occurring in many conditions associated with either defective food supply or absorption (as in some types of infantile dropsy) or in conditions of protracted anemia or cachexia is essentially the same as war dropsy. Hence the general term "nutritional edema" is to be recommended for this class of cases.

THE CAUSE OF ABSCESS OF THE LUNG AFTER TONSILLECTOMY

LOGAN CLENEDENING, M.D.

Instructor in Medicine, University of Kansas School of Medicine
KANSAS CITY, MO.

Reports of abscess of the lung following tonsillectomy have been appearing regularly in the literature during the last six years. Such cases are occurring fairly frequently in the practice of every man who pays any special attention to chest disease, and it is within the last few years that their presence has been so particularly noticeable.

What is the cause of this complication? Why has it made its appearance only lately with such frequency?

The first report of a case that I find is by Bassim.¹ I have not, however, been able to verify the reference. Shortly afterward Scudder² referred to it. The most comprehensive paper is that by Manges,³ published in 1916. Manges reports nine cases, in one of which the patient died. He discusses causation under the heads of (1) anesthesia; (2) aspiration of infected blood or of pieces of tonsillar tissue; (3) embolism, or infarction of the lung; (4) some special infective agent, and (5) some antecedent cause.

Perhaps only the last two heads need any explanation. Under the subject of some special infective agent he refers to three of his patients who were operated on in the same hospital, not far apart, and he

thought that possibly the fact that they acquired their disease at the same place and the same time bespoke the exposure to an infection with special pulmonary affinity.

For an antecedent cause he warns against operating when the patient has a cough, etc.

Manges made some statements in 1916, based on his own experience, which he probably would not repeat now. He states, for instance, that "abscess of the lung should never occur if the patient has been properly treated." He goes on to say that abscess of the lung never occurs after tonsillectomy in private practice. This is, of course, not true. Richardson,⁴ who published an article shortly after Manges, says that tonsillectomy is never a minor operation in an adult. He thinks these patients need more after-treatment than they get, and that every patient who is to have a tonsillectomy should have a thorough physical examination.

Coakley⁵ discussed the matter with particular reference to Manges' paper. His remarks are somewhat critical of Manges. He says that all his patients are carefully examined before a tonsil operation, and asks Dr. Manges to state just what he would consider a complete examination, and specifically just how it would prevent any lung abscesses.

Manges thinks, or thought in 1916, that all these cases were due to careless treatment on the part of the operating surgeon. He is, however, very hazy as to what was done that was careless. He thinks the head should be lowered during the stage of anesthesia and that the patient should be carefully examined before the operation to see that he has no pulmonary infection.

No idea of etiology has been advanced which bears the test of close scrutiny. It is admittedly true that poor physical risks, that patients with fresh tonsillar infection, and patients with acute respiratory disease are not good subjects for tonsillectomy. But carefully examined patients, persons of all ages in the best of health other than their tonsillar disease, patients with no respiratory infection, and patients surrounded with every care, attention and operative safeguard all get abscesses occasionally when their tonsils are removed by a skilled operator. The subjoined case is cited as an example of one occurring when every care was exercised:

An unmarried woman, aged 36, had her tonsils removed, July 1, 1918, on account of frequent attacks of tonsillitis. Her general nutrition was poor, and it was thought that the removal of the tonsils would improve that condition. The operation was performed in a hospital under general anesthesia. The anesthetic was administered by Dr. H. C. Anderson, who has devoted special attention to anesthetics for twenty years, and has had his widest experience perhaps in nose and throat operations. Furthermore, he took particular pains with this patient as she was a valued friend and co-worker. The operator was Dr. J. M. Patterson, a skillful and careful nose and throat surgeon. The anesthetic was gathered with a suction tube, and the flow of ether was maintained by a small pump engine. Every precaution was taken against aspiration of blood or infective material. The suction tube was never out of the patient's mouth. The operation was not troublesome and there was no excessive bleeding, either during the operation or later.

The after-course was instructive. The history of lung abscess began while the patient was on the table. She began to cough immediately after the operation was completed, and continued after she was put to bed. Only after the administration of one-half grain of morphin in divided doses was it

1. Bassim: Thèse de Paris, 1913, No. 181.

2. Scudder, C. L.: Boston M. & S. J. 171: 523 (Oct. 1) 1914.

3. Manges, M.: Am. J. Surg. 30: 78 (March) 1916.

5. Coakley: Laryngoscope 26: 1003 (July) 1916.

at all controlled. After the patient got up and around she continued to cough. In the course of a few weeks she lost several pounds, and with her coughing brought up a thick mucopurulent expectoration. The sputum was examined repeatedly for tubercle bacilli, always with negative results. A vaccine was prepared and administered without benefit. About two months after the operation she went to Colorado and stayed some time, but was not improved.

About eight months after the operation, examination of the chest revealed these physical signs:

Heart: No hypertrophy; sounds muffled but clear; pulse regular and strong, rate of 70 to 80.

Lungs: Percussion of right side in front, hyperresonant. Impaired percussion note in back at base. Whispered voice over this area heard faintly. Vocal resonance increased. On auscultation from angle of scapula down, fine crepitation on inspiration and beginning of expiration sometimes distinct, sometimes faint. Lungs otherwise unimportant. Apexes quite clear.

Roentgenoscopy revealed an indefinite shadow on the right side.

A puncture was made on the right side in March, 1919. The needle did not produce any pus for some time, and then at the third puncture entered apparently an air space, and a few flakes of pus and tissue were drawn up.

The patient refused thoracotomy.

In September, 1919, she submitted to a pneumothorax artificially produced on the right side, which has given some relief.

COMMENT

Here is a case carefully cared for by a careful man. The symptoms of lung abscess began immediately.

Motor driven anesthesia apparatus used in tonsil operations may be responsible for the inspiration of septic material and the resulting lung abscess.

I do not here refer to the suction feature of these machines, but to the motor which forces the ether vapor into the pharynx. These ingenious little mechanisms force ether into the posterior pharynx, under what is really a very high pressure. The pressure balloons out the posterior space, and is sufficient to create an air current that would force pus, infected blood clots, or infected pieces of tissue past the glottis into the lung. Its pressure is continuous. It impedes coughing. Even with the head in a low position the material accumulates there, and is forced downward.

These motors furnish a very good field for the operator. But most of our lung abscesses have resulted since their introduction. Neither Manges nor Richardson publishes facts which let us know whether motors were used in their cases. I have records of two other cases in which they were used. In both these cases a lung abscess developed after a tonsillectomy in which a motor-driven apparatus was used for anesthesia. In two other cases, bronchopneumonia developed under the same circumstances. Certainly the use of these motors should be discontinued until we are able to determine whether they operate as a cause of the distressing, crippling and hideous sequelae of tonsil removal.

In those cases in which no motor-driven apparatus was used I have turned as an explanation of the etiology to other facts.

There is a relation between the tonsil and the lung which has not sufficiently been dwelt on. I will cite briefly one case as an illustration:

A man, aged 44, complained of continued cough. It had followed an attack of influenza, and had continued several months. He had been told he had tuberculosis. Physical examination, sputum examination and roentgenograms all made this doubtful. The signs in the lungs were, in fact, completely negative. Yet he spit up about half a pint of

material a day. The tonsils were found badly infected. After their removal, the cough and expectoration promptly cleared up.

In other words, I believe that there is a path of infection directly from the tonsil to the lung, probably through the lymph glands. Definite information on the subject, however, is curiously lacking. The description of the lymphatic drainage of the tonsils in the standard textbooks on anatomy are very vague on the lymphatic chain after it reaches the deep cervical. However, Grober's⁶ experiments with India ink seem to indicate that there is a direct pathway between the tonsil and the apex of the lung. The tonsils have long been regarded as a possible primary focus of infection in pulmonary tuberculosis.

The relation of infection of the tonsils to the lungs is so close that operators should think seriously of it. When the tonsils are removed, there has been opened up a large area of raw surface, ready for any septic infection and possibly draining directly into the lungs.

Let that area alone. I do not know exactly how much dabbling around tonsil operators do on this surface, but it is my impression that they do a great deal. I see no good reason for trying to get out every particle of tonsillar tissue; it is nearly impossible anyway unless done at the first step of the operation. Stop swabbing it, fingering it, poking around in it. There is another aspect to the matter: Tonsil operators, to retain the confidence of the rest of the profession, must find some way to control hemorrhage, so that we do not have this dangerous packing and handling of a raw surface in the face of a septic cavity ten or twelve or twenty-four hours after it has been opened up. One of Richardson's cases of lung abscess occurred after a postoperative hemorrhage.

CONCLUSIONS

1. Lung abscess is at present a frequent sequel to tonsillectomy.
2. It occurs in all classes of cases—in private as well as in free services.
3. It is sometimes fatal, always serious and often very crippling.
4. It is due in some cases to inspiration of infected material.
5. Motor-driven anesthesia apparatus, by creating a positive pressure in the pharynx, may operate as a cause. At any rate, the danger is sufficiently great to justify the discontinuance of their employment until comparative data can be secured.
6. It is due in some instances to metastatic infection through the lymphatics.
7. Swabbing or tampering with the throat after enucleation has been accomplished is the cause of one group of cases.

6. Grober, quoted by Ballenger: *Diseases of the Nose, Throat and Ear*, Philadelphia, Lea & Febiger, 1911.

Insecticides.—Such substances as coal oil, gasoline, and benzine are very good insecticides for such more or less stationary parasites as the louse and the bedbug. They act by covering the breathing pores of these insects, and so smother them. These oily substances are also very useful in campaigns against mosquitoes in which they are used to form a coating over ponds and other bodies of water harboring mosquito larvae, thus smothering them with the film on the surface of the water which the larvae and pupae are unable to pierce with their breathing tubes.—*U. S. Nav. M. Bull.*, January, 1920.

HAND AND FOOT PRINTS AS RECORDS
IN LESIONS OF THE PERIPHERAL
NERVES

LEWIS J. POLLOCK, M.D.

Assistant Professor of Neurology, Northwestern University
Medical School
CHICAGO

Graphic methods of recording signs and symptoms in many instances have a greater value than descriptive

finger except the tips. The hypothenar muscles are seen to be atrophied by the presence of a notch on what normally consists of a rounded contour made by these muscles (Fig. 1 *a*). Between the mounts of the ring and middle fingers is seen another notch, and when the atrophy is very severe a notch appears between the ring and little fingers as well (Fig. 1 *b*). The fingers cannot be spread apart, and the first phalanx of the thumb is in a position of extension. The atrophy of the adductor pollicis is seen by a break in the line along the radial border of the base of the index finger (Fig. 1 *c*).

Median nerve lesions show very clearly the disturbance of the whorl formation on the tips of the index and middle fingers (Fig. 2 *a*). When severe clawing is present in these two fingers it is marked by the imprint of the very tips, frequently including the nail. The atrophy of the thenar eminence is usually well marked, and is shown by the prominence of the base of the thumb and a considerable notch in the normally rounded contour of the radial border of the thenar eminence (Fig. 2 *b*). The distal phalanx of the thumb is in extension. When severe clawing is present it is made evident by the absence of any imprint of the central portion of the palm. Not only is the atrophy of the thenar eminence noted by the notching proximal to the base of the thumb, but in many instances the loss of tissue is demonstrated along the radial border of the first phalanx of the thumb (Fig. 2 *c*). The

methods. Frequently it is impossible to have photographic records of the hands and feet in cases of peripheral nerve lesions; under this condition I have found it serviceable to record the contour of the palm and sole, by making impressions of the hand and foot.

Attention has been called to some of the changes seen in the conformation of the whorls of the skin in the various peripheral nerve lesions.¹ Imprints of the hands and feet are of greater value, however, than to demonstrate such changes alone. Not only is the position of the hand determined, but the atrophy of muscles and contractures are shown as well. Only five of the peripheral nerves show distinctive changes in a sufficiently large percentage to make it profitable to study the lesions by this method. These nerves are the ulnar, median, radial, internal popliteal and sciatic. The picture produced by a combined lesion of the ulnar and median is likewise distinctive. When the external popliteal nerve lesions show a characteristic picture, it is the same as that produced by lesions of the internal popliteal nerve.

Imprints of the hand in a case of a lesion of the ulnar nerve show the following characteristics: The clawing of the inner two fingers is well demonstrated by the absence from the imprint of any part of these

Fig. 2.—Imprints in case of median nerve lesions: *A*, affected; *B*, affected; *C*, normal; *D*, affected; *E*, normal; *F*, affected; *G*, normal; *a*, disturbance of whorl formation at tips of index and middle fingers; *b*, prominence of base of thumb and notch in contour of radial border of thenar eminence indicating atrophy of thenar eminence; *c*, loss of tissue along radial border of first phalanx of thumb; *d*, failure of desquamation and presence of many new lines over thenar eminence.

failure of desquamation and the presence of many new lines is demonstrated over the thenar eminence (Fig. 2 *d*).

Radial nerve lesions are characterized by the cramped appearance of the fingers which results from the inability to place the palm on the paper in a flattened

1. Cestan, R.; Descomps, P., and Euzière, J.: Bull. et mém. Soc. méd. d. hôp. de Paris 40: 652 (May 5) 1916.

position. The most characteristic feature of this imprint is the position of the thumb, which is adducted, the distal phalanx falling within or on the border of the outline of the index finger. The thumb is rotated about its own axis inwardly so that the imprint of the radial border of the distal phalanx is straight and not rounded, because of the thumb nail. The distal phalanx of the thumb is usually flexed. Absence of the

THE THÉZAC-PORSMEUR METHOD OF SUN TREATMENT

ROBERT W. LOVETT, M.D.

BOSTON

In the spring of 1919, a new method of applying heliotherapy by means of a lens was called to my attention by Mrs. Edward C. Post of Newport, in whose sanatorium at Porsmeur, Morlaix, Brittany, it had been used. The lens had been called to her attention by M. de Thézac, and was put into practical use at the sanatorium by Miss Helen Whidden, the trained nurse in charge of the day camps, who was familiar with the Rollier and Malgat methods of sun treatment. Another treatment by a lens has been described by Artault.

In this paper I shall describe a series of carefully observed cases of chronic suppuration in the orthopedic service at the Children's Hospital, in which the treatment was by the Thézac-Porsmeur method. Miss Helen Whidden, who had charge of the treatment in France, was so good as to devote three months to the demonstration of it at the Children's Hospital.

The essential of the treatment is the concentration of the sun's rays by means of a double convex lens with a diameter of 12 inches and a focal length of 72 inches. At the focal point, of course, the heat is very great, as it would be in any lens used

Fig. 3.—Imprints in case of radial nerve lesions: A, affected; B, affected, musculospiral, operated on, April 22, 1919; C, normal; D, normal; E, affected, paralyzed abductor pollicis; F, normal; G, affected, musculospiral, operated on, April 4, 1919.

signs of atrophy of the thenar and hypothenar eminences is an additional feature of this form of lesion.

In combined lesions of the ulnar and median nerves, signs of atrophy of both the thenar and the hypothenar eminences are demonstrable by means of the notches found along their borders (Fig. 4 a). Clawing is present in all four fingers. The mounts are often separated (Fig. 4 b). The center of the palm shows a larger area in which no imprint is seen. When, in addition to the ulnar and median, the radial nerve is involved, the thumb shows at times the same rotation as was observed in radial lesions.

In lesions of the external popliteal nerve there is frequently seen a flattening of the toes, so that the plantar surface of the entire length of a toe will produce an imprint.

Lesions of the sciatic nerve show in addition to a slight pes cavus in some cases, a clawing of the toes indicated by the absence of their imprint on the paper.

It may be stated that, although by no means diagnostic, such records are of considerable value in determining the progress of the condition of atrophy and deformity in peripheral nerve lesions.

The imprints are very easy to take, and require a minimum of time for the amount of record produced.
25 East Washington Street.

Fig. 4.—Imprints in case of ulnar and median, and ulnar median and radial lesions: A, ulnar and median; B, normal; C, ulnar and median; D, ulnar and median; E, ulnar and median; F, ulnar median and radial; G, brachial plexus; a, notches indicating atrophy of thenar and hypothenar eminences; b, separated mounts.

as a burning glass, and in general the patient should be placed at a point where the sun's rays form a circle of from 3 to 5 inches in diameter.

As the patient is moved farther away from the lens, the heat increases, and as the patient is moved nearer

the lens, the heat diminishes. The degree of activity to which it is desirable to submit the wound can be regulated by carrying the lens nearer the patient or farther away.

The lens is mounted in a canvas cylinder, 1 foot in diameter and 3 feet in length, which is kept rigid by two circular wires with thin strips of wood running from one hoop to the other, over which the canvas is stretched. The lens is placed a few inches from one end of the cylinder. The advantage of this cylinder is that it enables the lens to be pointed directly at the patient and makes the application of the treatment more definite. The cylinder carrying the lens is mounted on a tripod and can be swung in any direction by means of a handle.

The duration of the sun treatment should lengthen progressively. The first treatment should last for five minutes and increase at the rate of about five minutes a day up to thirty minutes. In a certain case a longer period up to an hour and a half was used without apparent ill results. The skin around the wound was as a rule protected by towels, and the person giving the treatment wore colored glasses, as the light is extremely bright, and the eyes of the patient were protected if exposed to the glare of the circle of light. The patients were given one treatment a day.

The effect of the treatment on suppurating wounds was perfectly definite: (1) The discharge immediately increased and then diminished; (2) pale granulations took on a healthier color, and (3) sensitiveness diminished. In order to test the efficacy of this treatment, a series of suppurating wounds of the severest type was selected, and cases that were obviously difficult. In the wards in a hospital for acute cases it was necessary to select a more acute type than would have been the case in an institution for chronic diseases, as patients that were doing well were discharged to the convalescent home on account of the need of beds, and chiefly the chronic suppurations that were resistant remained long enough to be observed under this treatment.

The cases here reported were observed by members of the staff, and records were dictated by them as to the progress of the cases.

REPORT OF CASES

CASE 1.—*Tuberculosis of the Hip.*—M. M., a boy, aged 7 years, had had tuberculosis of the left hip of one year's duration, during which time in spite of treatment he had made bad progress and showed very little resistance. The von Pirquet reaction was positive, and he had had some abscesses. He seemed to have no power of repair, and had large areas of pale, flabby granulations which were melting down into larger ones, with much glandular involvement. Operation seemed out of the question on account of the extent of the infection, which extended half way to the knee. In April his parents were advised to take him home, as the case seemed hopeless. This they were unwilling to do. In May he was very much emaciated and septic. There were two sinuses around the hip, and a granulating area 4 inches long in his leg. He was extremely sensitive to motion and very lethargic. From May 1 to August 27 he received fifty-five sun treatments.

June 19, the wound was smaller and looked more healthy. Sensitiveness was much diminished, but the temperature remained high. Discharge had increased, the bacterial count had fallen from 25 to 4 streptococci, and from 15 to 2 staphylococci, and the pyocyanus had disappeared after five days.

July 7, the wound on the leg had nearly healed, and the general condition had greatly improved.

July 31, the lymph nodes had diminished greatly in size.

August 6, the temperature became normal in the morning, but rose in the afternoon to 100 or 101.

August 27, when the treatment was discontinued, the large wound had nearly healed, the boy was well nourished and had a good color, and he was happy and full of interest.

Here was a serious tuberculosis of the hip regarded as hopeless, whose repair was definitely stimulated, and whose local and general condition was greatly improved after treatment was begun. As for months previous to this the patient had been going down hill, and as no other change in

Fig. 1.—Method of applying lens treatment.

his treatment had been made, in the opinion of all who observed him the gain was to be attributed to the treatment by the lens. The bacterial count did not remain permanently low, but the streptococci rose slightly, August 20.

CASE 2.—*Congenital Syphilis.*—M. S., a girl, aged 12 years, had had congenital syphilis with destruction of bony tissue of the right ulna, and extensive skin ulcerations of three years' duration. There was an affection of the right wrist of one year's duration, the diagnosis apparently not having been made. Numerous small sequestrums were present in the wound, which were detached as they became loose. There was an ulcer at the elbow joint 3 inches in diameter with regular sharp edges and exuberant granulations which were greenish looking and soft; there was an ulcer at the lower third of the forearm, ulnar side, sloughing and discharging freely, and a roentgenogram revealed destruction of bone beneath both of the ulcers mentioned.

The patient was given thirty-three sun treatments aggregating twenty-one hours, covering a period from May 8 to August 5. The elbow was treated by heliotherapy. The patient had been receiving antisyphilitic treatment and the wound on the elbow had nearly healed, but the wound on

the wrist showed no disposition to heal and remained open. The Wassermann reaction was positive, and since April 3 the patient had been given 5 grains of potassium iodid three times a day with 2 grains of mercury with chalk. Later, no improvement occurring, the wound was dressed with mercury ointment and the patient was given arsphenamin intravenously, April 26, and three subsequent doses in the early part of May. The mother's Wassermann test was reported positive. In two months the elbow had entirely healed except for a small place where a bone spicule was protruding; and at discharge, both wounds were healed. The bacterial count fell from an average of 25 streptococci in the first four exposures to an average of 8 in the last four before the wound closed, and the staphylococci fell from 6 to 3.

This was a case of long-continued bone suppuration from syphilis which had been under antisyphilitic treatment without healing of the wound. The case was very extensive, and although the patient was having the antisyphilitic treatment, the improvement seemed to begin only when the sun treatment was started. The effect was most striking in the very rapid healing of the wound which began after the heliotherapy was commenced.

CASE 3.—Acute osteomyelitis of left femur.—A boy, aged 8 years, had acute osteomyelitis of the left femur. The involved area was incised, April 20, 1919. May 16, when the sun treatment was begun, there was profuse drainage and a temperature running at night often to 104. June 2 the sun treatment was discontinued. It was tried, June 27, but was again discontinued. July 3 it was begun again. August 27, when treatment was discontinued at the hospital, the wound was beginning to close and the discharge was small. The patient had to be operated on in October, 1919, and received Carrel-Dakin treatment, and on November 26 the wound was practically healed. The temperature was normal for two months, since September.

Only twenty-six treatments, aggregating nine hours in all and covering 100 days, were given, the treatment having been interrupted by extensions of the process in the bone. The bacterial count did not fall, but the wound made good progress and grew smaller, the color of the granulations improved, and the sensitiveness diminished during the periods of insolation. The case showed that the treatment was not as well adapted to acute osteomyelitis as to the more chronic conditions, although it seemed to have a stimulating effect on the discharging wounds; but the process in the bone was still progressing, and nothing but operation could give final relief.

CASE 4.—Cellulitis of right tibia.—A girl, aged 8 years, had cellulitis of the right tibia. The involved area was incised, June 12. When sun treatment was begun there was a wound 3 inches in length, and at the back of the leg a wound 7 inches in length with considerable discharge. When the sun treatment was discontinued there remained only two small areas, one at each end of the anterior wound, which were quite dry, the posterior wound leaving a strip 3 inches long and one-fourth inch wide which persisted, which it was deemed more rapid to close by suture.

There were twelve sun treatments, covering a period of thirty-six days between June 24 and July 31. During the sun treatment the wounds became less sensitive and much healthier in character. The streptococci were reduced to about one third of what there were at the height of the infection, but the staphylococci, which were about 5 to a field at the beginning, remained about the same. The patient was discharged in good condition, August 20.

This was a case of suppuration of the soft parts, with no bone involvement, in which the sun treatment had a very stimulating effect on the closure of the wound.

CASE 5.—Acute osteomyelitis.—A girl, aged 11 years, with acute osteomyelitis, underwent operation, March 19, with incision and drainage. A second operation was necessary, July 1, and on July 12, when the sun treatment was begun, there was a very sensitive wound, draining profusely with a foul smelling greenish discharge. Twelve treatments in all were given, covering a period of forty-three days.

July 31, it was noticed that the wound was in decidedly better condition.

August 27, there remained only a small granulating surface about one-fourth inch in diameter, which was the opening of a small sinus. At the outside of the leg there was a small granulating surface communicating with the bone. The general condition was much improved and, August 28, the wounds were discharging very little, and the patient was sent to the convalescent home. The bacterial count of streptococci remained about the same. The case was regarded as having made better progress than it would have done without the sun treatment. This was an exceedingly deep-seated and resistant suppuration which immediately improved on the beginning of the sun treatment.

CASE 6.—Osteomyelitis of right tibia and left foot.—A boy, aged 9 years, who had osteomyelitis of the right tibia and left foot since April, 1919, was operated on for bone drainage, June 4. When the sun treatment was begun, the wound of the tibia was 17 inches long and 2 inches wide, discharging profusely. Twenty-two treatments were given between June 28 and August 27, a period of sixty-one days. July 24 a loose piece of bone found in the wound was removed. August 28, the wound was almost entirely closed, and the wound on the foot healed quickly, leaving three small sinuses. Later a small ulceration developed in the scar. The patient was discharged September 19. It was evident that from the beginning of the sun treatment the case healed with unusual rapidity.

Fig. 2 (Case 2).—Appearance of arm in May, 1919.

CASE 7.—Osteomyelitis.—A boy, aged 10 years, having osteomyelitis, received twenty-six sun treatments covering a period of sixty-eight days between May 24 and July 21. He had been in the hospital eight times since 1916, and had had several operations. When the sun treatment was begun there was a wound at the right area above the elbow $3\frac{1}{2}$ inches long, penetrating to the bone. July 15 the wound had healed except for a small area $\frac{3}{8}$ inch long and $\frac{1}{8}$ inch wide, at the center of which was a sinus communicating with bone. Streptococci fell from 25 to 4, and staphylococci from 10 to 2. This was a chronic low grade osteomyelitis apparently aided in the healing process by sun treatment.

CASE 8.—Tuberculosis of the spine.—A girl, aged 5 years, who had had very bad home surroundings, had a high dorsal tuberculous spine with pressure paralysis and involvement of sensation. A large ulceration developed on the back because of this lack of sensation, and wherever pressure was exerted a new ulceration developed. The sun treatment with the lens was inaugurated, May 8, and continued to May 31, to determine whether it would improve the sloughing on the back. The ulcerated area became smaller, but as the disturbance was evidently trophic in character the sun treatment was abandoned, as it was a case in which it was not likely to be of use.

CASE 9.—Osteomyelitis.—A girl, aged 10 years, with multiple osteomyelitis dating from October, 1916, had undergone several operations. Sun treatment was instituted in an abscess on the forearm 2 inches long and one-fourth inch wide. Eighteen treatments were given between May 8 and July 1, with the lens, and twelve sun baths. The wounds became cleaner and smaller, and on account of the child's having developed new foci, sun baths were instituted. At the end of the combined treatment with the lens and sun

baths, the wounds on the arm had nearly healed. The general condition was much improved. Pain had diminished.

The case was a very difficult one, under observation and treatment for many years, and very resistant to everything that had been attempted. The combination of lens treatment and sun baths seemed to have the effect of improving the healing process.

CASE 10.—Nontuberculous arthritis.—A girl, aged 7 years, who was poorly developed and nourished, had nontuberculous arthritis, which was most marked in the left knee, though there was some involvement of other joints. Blood culture was negative. The patient received six sun treatments between June 21 and July 3. No change in the condition of the joint was noted. Treatment was too short for any definite conclusion to be drawn, and the case was not suitable on account of its multiple character.

CASE 11.—Cervical Pott's disease with abscess.—A girl, aged 2 years, had a discharging tuberculous abscess. Sun treatment was started but abandoned because of the lighting up of the disease. Only seven treatments were given between June 21 and July 1, as the disease was increasing in the spine. The case was inconclusive.

CASE 12.—Dactylitis of the left hand and ankle.—A girl, aged 6½ years, had had dactylitis of the left hand and ankle of two months' duration. The case was clearly tuberculosis, and the bone was extensively involved. The von Pirquet reaction was positive. The pus from the finger was proved tuberculous by an inoculation in a guinea-pig. Eight sun treatments were given, and the parents took the patient home. No conclusion from the sun treatment can be drawn.

COMMENT

In my opinion and that of my associates, there was greater progress in the cases treated by the lens than there had been before, or than there had been in similar cases. Improvement in Case 1

was striking. The boy had been a long time under observation, he had made no headway whatever, and from the time the lens treatment was begun his improvement was rapid and steady. In two acute osteomyelitis cases in which the treatment was used within a week after operation, it seemed to be too stimulating, the temperature rose, and the sun treatment had to be deferred.

For six years I have had experience in sun treatment in which the whole body has been exposed, and I am a strong advocate of its value. I am equally convinced that the treatment with the lens is a distinct addition to our therapeutic measures, as it possesses decided advantages. It can be delicately regulated and controlled; it is applicable when the sun is sufficiently clouded to be useless for general exposure; and it can be used in a sunny room by opening the window and pointing the cylinder at the sun. It seems free from risk when used according to directions, and it seems to embody real possibilities.

A bacterial count was made in all cases at short intervals, and a study of the cases shows that the effect of the sun treatment was to lower immediately the bacterial count in the discharge in the wound; but in several of these cases there was underlying suppuration, and the bacterial count was naturally not affected.

The value of the treatment would seem to have been demonstrated in cases of chronic suppuration from tuberculosis, syphilis and chronic osteomyelitis.

234 Marlborough Street.

THE TREATMENT OF INJURIES TO ATHLETES

HARRY EATON STEWART, M.D.

Consultant in Physiotherapy, U. S. Public Health Service

NEW HAVEN, CONN.

We are now seeing a greatly increased participation in the various forms of athletics, especially of those types which are classed as the "vigorous fighting games of youth"—football, basketball, soccer, boxing, etc. The war has had a marked effect in stimulating participation in these sports. By contrast, also, the injuries that so often accompany indulgence in them now seem so trivial that many restrictions, especially against football, have been removed. The physician may therefore expect to see a great deal more of the special types of injury that occur in athletics than he has heretofore been called on to treat.

There are many comparatively new forms of physical treatment being thoroughly tested out in the physiotherapy departments of our army and Public Health Service hospitals which are especially applicable to the treatment of athletic injuries. Much of the good accomplished has been the direct result of the skill and untiring effort of the reconstruction aides—

young women well trained in the various branches, such as massage, electrotherapy, exercise and thermotherapy. They constitute a group having exceptional preliminary training and wide experience, and have not been deeply grounded in any one so-called "system" of treatment. These

young women are becoming available in increasing numbers, and are capable of rendering the physician invaluable help in treating many types of cases.

That physician who will spend the brief time necessary for a person with his background to inform himself regarding the technic, indications and contraindications of the simpler forms of physiotherapy will be richly repaid for his labor. He is often too busy to give these treatments personally, but he needs rather detailed knowledge in order to prescribe them properly. For instance, to order "massage" in a given case without seeing to it that the type used, duration and method of application are correct is almost as vague as to order medicine without stating the kind or the dosage. For example, hacking or deep kneading might be absolutely contraindicated in a given case, when gentle and long continued stroking would be of great value.

The treatment of athletic injuries is often a complicated problem. The patients are usually young and in exceptionally good general health. Focal infections do not, as a rule, play a part in delaying recovery, but they must be kept in mind. On the other hand, we have two difficulties to contend with: the necessity of using the injured member slightly at the earliest possible moment, as would be necessary in signal practice, kicking or goal shooting, in order to keep in touch with the game. In addition, pressure on the part of the coach and their own eagerness to resume play sub-

Fig. 3 (Case 2).—Appearance of arm in July, 1919.

jects these patients at the earliest possible moment to the very severe strain of the full contest. Time is always the most important factor.

The application of the various types of physiotherapeutic treatment to injured men of a university football team last fall brought very satisfactory results, and it is with the hope that interest will be stimulated in the conservative use of these treatments by the profession that this paper was written. The patients treated were referred through the courtesy of Drs. Townshend, Greenway and Cook.

CLASSIFICATION OF INJURIES

Most of the injuries due to athletics fall into one of these classes: (1) muscle bruise; (2) torn ligaments; (3) torn muscle insertions; (4) subperiosteal hematoma, or (5) tenosynovitis.

Muscle Bruise.—This injury is perhaps the most common we meet in football players. It is usually caused by the shoulder of the tackler hitting the runner with great force on the front of the thigh. There follows at once pain, weakness, swelling and stiffness of the extensors of the leg.

The pathologic condition varies with the force of the blow and the hardness (condition) of the player. There may be only a slight bruising, which massage at once and continued light use will entirely eradicate. Generally, however, the muscle fibers will be found torn and matted together with considerable extravasation of blood and lymph.

The muscle should be relaxed, bandaged firmly, and rested twenty-four hours. After that period, treatment by the application of heat is begun. Baking is good, but does not penetrate deeply as the high frequency does. This current is usually given in the form of direct diathermy. A still more efficacious and better controlled method is by indirect diathermy. With the patient on the autocondensation pad or cushion attached to one pole of the d'Arsonval current, the other pole is applied directly over the injured muscle by the vacuum or, better still, a nonvacuum electrode. It is important to keep this electrode moving rapidly over the surface. A little powder applied to the skin will aid in the ease with which the electrode can be moved. Care must be taken that the cords are well insulated; a piece of rubber tubing will serve the purpose. If a steel table is used, one should avoid any possibility of the patient's touching the table during the treatment.

Massage is begun the second or third day, very gently at first, only effleurage (stroking) and light pétrissage (kneading) being used. During succeeding days the massage should be given with greater vigor. Tapotement (hacking) or even the high powered motor vibrator may be necessary to free the muscle fibers. These measures should be resorted to at once when the case is not seen until several days after the injury.

In a few of the cases the injury was at first deemed slight and received vigorous treatment at the hands of

the team "rubber." Here capillary bleeding was again set up, with increased disability the following day. In very slight bruises this treatment would do no harm.

Torn Ligaments.—Sir Robert Jones has given us the key to the proper treatment of these injuries: relaxation, partial protection, and guarded but constant use. Let us take, for example, a tear of the external lateral ligament of the ankle. Raising the outer side of the heel and a reversed flat-foot strapping would secure the relaxation and protection necessary. Gradually increased walking on the level with a graded schedule of carefully applied passive, active and resistive movements will bring quicker results than complete immobility, which is often followed by a long period of distressing stiffness. In addition, the use of heat, diathermy, and massage will greatly hasten the repair process.

Torn Muscle Insertions.—These injuries are encountered in football and basketball, but are most common in track athletics, frequently following sprints and sprint starts before the runner has thoroughly warmed up. The general course of the treatment is the same

as that already outlined, except that the relaxation must be complete, secured by splints or sand bag, if necessary, and held for at least two weeks before active treatment is instituted; and care must be taken not to tear the newly formed attachment.

Subperiosteal Hematoma.—This is the true "Charlie horse" for which the muscle bruise is so commonly mistaken. It should be treated by rest and firm bandaging until the hemorrhage has stopped, and then by heat and massage to promote absorption of the clot. The massage should be confined to frictions and deep stroking.

Tenosynovitis.—We find this condition early in the season in most sports, and generally confined to the Achilles tendon. It may follow the distance runner all through the track season. Acute conditions demand absolute rest, heat and gentle stroking. I have seen a number of chronic cases in college and preparatory school runners lately which cleared up with remarkable rapidity when treated with indirect diathermy and massage. In some of these cases the tendosynovial fluid will be found inspissated, and at times solidified and broken up. More prolonged and intense heat and massage with friction are indicated.

1173 Chapel Street.

Direct diathermy in treatment of shoulder injury

Health and Education.—A very significant trend in education during the past few years is shown in the recognition that health is fundamental to sound intellectual development and that the rigid regulation of all things pertaining to the hygiene of students is indispensable. Generally speaking, there is serious economic and academic loss year after year in our schools, colleges, and universities, due to lassitude, indisposition, illness, and epidemics among students, all more or less preventable.—John Sundwall, *Pub. Health Rep.*, Nov. 7, 1919

Clinical Notes, Suggestions, and New Instruments

A NEW BRACE FOR TUBERCULOUS SPINES

GORDON N. MORRILL, M.D., CLEVELAND

In the treatment of ambulatory cases of Pott's disease, an adequate means of holding the spine in hyperextension is of vital importance. This is obviously more difficult of attainment than when the patient is recumbent on a frame, because of the strain put on the brace by the bending forward of that portion of the trunk which is above the deformity. A device which I have found satisfactory for this purpose is of the type illustrated here—one which I have used exclusively and with uniform success for the last eight years in all convalescent cases of middorsal and lumbar tuberculous spines. It owes its value as a curative element, not to rigidity or to a great amount of fixation, but to the three-point pressure secured with correct adjustment: first, pulling back on the shoulders; second, pressing forward on the kyphos, and third, pulling back on the pelvis.

From the accompanying illustrations, the appliance may be recognized as practically a reconstituted spring-back brace, differing in the main only in the greater rigidity of the material used, and in the diminished distance between the uprights. Its simplicity of construction and adjustment is apparent. Two upright pieces of steel, placed only a sufficient distance apart to prevent impinging on the spinous processes, are joined above by a steel cross-piece at a point slightly higher than the posterior level of the armpits when the arms are hanging, and below by a wider steel band attached to the uprights approximately at a level with the center of the sacro-iliac articulations, sloping slightly

of the shoulder straps—a factor of vital importance, since the shoulder weight alone is responsible for preventing the brace from sliding upward; but occasionally perineal straps must be resorted to when the brace will not maintain a correct position by the usual means. The abdominal band is specially constructed in accordance with the peculiarities of individual cases. For the patient seen in Figure 2, a lumbar case, I have used a leather belt with side lacings and anterior straps of webbing to insure very accurate adjustment. When this seems unnecessary, the lighter weight webbing belt is sufficient if designed as in Figure 4, so that the double lateral strappings are merged into a single abdominal band reinforced by vertical stays, usually three in number and placed at intervals. The pelvic band is buckled to the ends of the lower cross-bar (Figs. 1 and 2), and from them it passes directly below the anterior superior spines.

All steel parts of the brace are well padded, particularly at the points of greatest pressure, with the exception of the upper cross-bar, which does not come in contact with the patient. In the case of the boy in Figure 1, in whom the kyphos was of considerable size, I used the customary padding of felt and leather, with additional thickness on each side of the kyphos, where, in order to secure the desired amount of correction, the pressure was extreme.

To any one familiar with the type of brace commonly used in these cases, the absence here of the customary canvas or leather apron for securing the proper degree of fixation will be noticeable. In my opinion, it is one of the most commendable features of the appliance. This apron, which extends from the clavicles nearly to the symphysis pubis, is fastened to the brace by several nonelastic straps on each side, and is supposed to be strapped as tightly as

possible. The unavoidable result is a flattening and compression of chest and abdomen to such an extent that normal development is rendered improbable. My patients' chests are

Fig. 1.—The brace applied in a case of dorsal Pott's disease in which there is a large kyphos; extra padding at the seat of the disease.

Fig. 2.—Three views of the brace fitted in a case of lumbar tuberculosis; the freedom allowed the chest is a most commendable feature of the device.

Fig. 3.—The patient seen in Figure 2, wearing clothing over the brace; the excellent posture may be noted.

downward, and curved to fit the patient. As a rule, the brace is held in position by means of three strappings—those about the shoulders, the abdomen and the pelvis. The shoulder straps, attached as illustrated, pull the shoulders backward, forcing the forward-sagging portion of the trunk above the kyphos to straighten when, with the kyphos as the fulcrum and the brace as the lever, the device is forced into position and the pelvic band made secure. The angle at the top of each upright bar makes possible a very accurate adjustment

unconfined, their expansion is increased rather than diminished as is the case when the apron is used, and their normal development is therefore encouraged instead of retarded.

The value of the brace as a curative factor, however, depends, as I have previously stated, on its correct adjustment—a fundamental point, and one which cannot be over-emphasized. It should be made to fit the individual patient, the curve of the uprights so arranged as to assure the requisite amount of spinal hyperextension. If there is a

slightly reddened area on each side of the kyphos when the brace is removed, the physician may be certain that the desired three-point pressure has been secured. Even so, unremitting watchfulness is necessary, making essential the procuring of monthly tracings, and, consequently, as frequent careful readjustment of the support to coordinate with any change of the kyphos, and to take advantage of a resulting possible improvement in posture. While the brace is being altered, and when it is removed daily for the alcohol rub and the powdering which the back must receive—as well as whenever it is applied—the patient should lie face downward

with the spine as nearly immobile as he can hold it. He should in no contingency sit or stand erect when without the support; nor should he be permitted to bathe himself or be given baths in a tub by the attendant, until at least a periodic removal of the brace has been ordered by the physician.

When the condition of the patient seems to justify removal of the brace, he should go without it for only short periods at first, increasing them gradually as the physician may direct. And these periods of freedom should always be during the waking hours until such time as an exacerbation of the disease seems very unlikely. The reasons for this should be obvious: When conscious, the patient will instinctively avoid motions and postures which would be painful and therefore irritating to the weakened area; but while sleeping, a sudden turn or twist might easily impair restoration which had been the result of years of patient endeavor.

Fig. 4. — Arrangement of pelvic and abdominal strapping frequently resorted to, especially with young children.

The cases illustrated here will serve to make clear my points as to the construction and adjustment of this brace. But only experience and a fair trial can convey any adequate notion of its efficacy in cases affecting the dorsal and lumbar regions.

NEW FRACTURE BAND

ASA W. COLLINS, M.D., SAN FRANCISCO

Many years ago a case of comminuted fracture of the lower end of the femur, which seemed impossible of reduction, suggested to me the necessity of devising some method whereby the fragments could be accurately apposed and held in normal position. After considerable thought, together with a number of experiments, I devised the band with an instrument for its application, which, after many modifications, I am offering to the medical profession as one more addition to the many appliances used in operative work on fractures of the long bones.

Wire, when sufficiently tight to possess the proper tensile strength, breaks or loosens. Screws crack and destroy the bone, as well as loosen. Pegs are uncertain for the same reason. Plates are held by screws and are defective in some cases on account of the breaking or loosening of the screws. A single band around a bone does not possess a sufficient amount of strength to immobilize the fragments, and the slightest lateral motion is enough to cause an erosion and necrosis of bone beneath the band. Ligatures are difficult to apply, and often cut or break. Grafts are accompanied by great destruction of tissue and too often become sequestered, and so one is baffled many times in trying to decide on the use of any one or two methods which will meet every requirement. The prime factor in treatment of fractures of bones is a restoration of function, and this is dependent on securing proper apposition and maintaining it. Happily, the treatment is not often difficult, and the results are excellent in the great majority of uncomplicated fractures in the long

bones; but it is in the consideration of the exceptional cases that we are now concerned, for it is here that the resources of the surgeon are not infrequently taxed to the uttermost.

In this band we have a method which does not necessitate further destruction of tissue,

Fig. 1. — Band surrounding fractured bone, with instrument for tightening and locking the band. The width of the metal of the bands used at the present time is slightly narrower than those shown in the illustrations.

Fig. 2. — When the instrument draws the band sufficiently tight, the band is locked by being bent on itself. This is accomplished by pushing on the instrument, which causes it to bend, as shown.

Fig. 3. — Before and after applying a band in a typical case in which the band is best indicated. A large callus developed, and the patient has perfect functional result after a period of nearly two years.

such as screw holes, boring and sawing. The fragments are brought together by simple, even pressure, and are held until regeneration is complete.

In the thirty-four cases in which operation was performed, it was not found necessary to remove the band in a single instance, as all the operations were successful, the band becoming firmly embedded in the callus. The bands are made of an alloy of silver and nickel and heavily plated with pure silver, which gives them all the necessary requisites, namely, tensile strength, ductility, malleability and noncorrosibility. They are thin, and occupy very little space. The instrument for applying the band, as illustrated, will readily exemplify to the surgeon the simplicity with which it can be used. Up to the present time only two sizes of bands have been used, each with one window. The cases in which the use of the band is indicated are oblique and comminuted fractures of the femur and humerus. The band has also been applied on other long bones successfully.

To apply the band it is first bent so as to pass around the bone, and then into the instrument, where it is firmly held by a screw passing through a small hole in the band. It is well to remember to begin by passing the small end or tongue of the band around the bone first, beginning underneath the bone, and then passing it completely around the bone before pushing it through the window or loop. The band is tightened by turning the handle of the instrument until the proper tension is secured, when it is immediately locked by simply pushing on the instrument, which automatically locks the band by bending it on itself. The next step is to unscrew the instrument so as to cut off the end of the band with a pair of scissors about half an inch from the point at which the bending took place, and then bend over completely with almost any kind of a blunt instrument; a pair of heavy Mayo scissors will answer the purpose of cutting the band.

This device is not offered with any intention of supplanting any other operative method instituted in the past; but it is a valuable addition to the armamentarium used in operative fractures of long bones.

126 Post Street.

A SIMPLE METHOD OF MEASURING INTRACRANIAL PRESSURE

JOHN A. CALDWELL, M.D., AND CHARLES E. KIELY, M.D., CINCINNATI

Methods of measuring intracranial tension have in the past been extremely unscientific. The majority of observers have been content with observing the rate of flow, or, in cases of high tension, the length of the spurt of spinal fluid on withdrawing the stylet. From time to time, appliances have appeared, usually with elaborate three-way valves and with mercury manometers. The former are difficult to sterilize and the manometers are constantly aggravating because of the possibility of spilling the mercury. Further, the devices usually recommended are connected to the manometers by an adapter fitted into the butt of the spinal needle. This necessitates complete withdrawal of the stylet, and consequently involves, in cases of high pressure, a spurt of spinal fluid, which is lost entirely, before the adapter and needle are connected. This results in a lowered reading.

We have devised a needle in which a by-pass is added to the butt of a common puncture needle, with an adapter for a glass millimeter tube.

The needle free of the glass tubing is inserted in the usual way until the operator feels certain that he has entered the spinal canal. The measuring tube is then adapted, and the stylet of the needle withdrawn to the length of the attached chain. Unlike the standard needle, this one is of a constant bore through its entire length, so that when the stylet point has passed far enough out to permit egress of fluid into the

perpendicular tube there is still no avenue of escape through the end of the needle, as shown in the accompanying illustration. The pressure will, of course, be read directly in millimeters of spinal fluid in the graduated glass tube. When the specimen of spinal fluid is to be withdrawn it will be necessary only to remove the stylet entirely. If serum is to be administered, an adapter can be fitted to the by-pass.

We feel that this device offers several advantages: simplicity with consequent sterilizability; freedom from the annoyance of spilling mercury; greater accuracy of reading, as the column of fluid will be thirteen and six tenths times as long as that of mercury. Finally, it is to be noted that even in the highest pressures that will be encountered, the amount of fluid set free in the device will not reach 2 c.c., which will never be a dangerous withdrawal even in tumor cases.

628 Elm Street.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

BARBITAL (See New and Nonofficial Remedies, 1920, p. 82).

Barbital-Chiris.—A brand of barbital complying with the N. N. R. standards.

Manufactured by the Antoine Chiris Company, New York City. U. S. patent No. 782,739 (Feb. 14, 1905; expires 1922) by license of the U. S. Federal Trade Commission.

BARBITAL SODIUM (See New and Nonofficial Remedies, 1920, p. 83).

Barbital Sodium-Chiris.—A brand of barbital sodium complying with the N. N. R. standards.

Manufactured by the Antoine Chiris Company, New York City, U. S. patent No. 782,739 (Feb. 14, 1905; expires 1922), by license of the U. S. Federal Trade Commission.

CONDENSED VITALAIT.—A pure culture in vials of *Bacillus bulgaricus*.

Actions and Uses.—Condensed Vitalait is designed for internal administration. See general article, Lactic Acid-Producing Organisms and Preparations, New and Nonofficial Remedies, 1920, p. 156.

Dosage.—The contents of one vial in water or milk, just before retiring, is the usual daily dose. The cultures are distributed by the manufacturer only and are sent by mail. Each vial bears an expiration date.

Manufactured by the Vitalait Laboratory of California, Pasadena, Calif. No U. S. patent or trademark.

The culture is grown in sterile skimmed milk, its incubation period being twenty-two hours. The average bacterial count of the finished culture is stated to be 200,000 per Cc.

Practical Obstetric Teaching.—The provision of large maternity centers in various parts of London, fully equipped for the reception of lying-in cases and perhaps also for gynecologic cases, and certainly associated with maternity and child welfare centers, must be a feature of hospital evolution in the near future. The need for such centers is pressing, and once the public learns that the present death rate and the present dangers of child bed are almost entirely preventable they will not be content with the existing inadequate provision for the hospital treatment of such cases, they will demand, and rightly demand, ampler and better provision. And the public authorities will have to yield to their cry. The maternity centers will furnish opportunities of teaching undergraduates, postgraduates and midwives on a larger and better scale than exists at the present time; and it is the business of the teachers of midwifery to take advantage of opportunities that may offer for the institution and management of the centers.—*Lancet*, Dec. 13, 1919.

Design of needle for measuring intracranial pressure.

PROTECTION AGAINST POLIOMYELITIS

Whenever a disease breaks out in epidemic proportions nowadays, widespread advertising of protective measures is almost certain to follow. Owing to the known involvement of micro-organisms or similar infective agents in the genesis and spread of such diseases, the use of antiseptics is usually promptly lauded, particularly by those who are interested in the sale of alleged germ-destroying products. It is now generally believed that the inciting micro-organism or virus of poliomyelitis enters the nervous system by way of the nasal passages. This, therefore, has raised the question whether, during an epidemic of poliomyelitis, the application of antiseptics to the nasal mucosa is to be recommended.

The extent of present-day information regarding the fate of the virus in the human body is still too limited to make new possibilities of prophylaxis appear inconsequential. In considering the possibility of local antiseptic treatment, Flexner and Amoss¹ of the Rockefeller Institute for Medical Research have pointed out that in the case of chronic meningococcus carriers, the suppression of that micro-organism by the introduction of antiseptics directly into the nasopharynx has not been notably successful; and they state that the meningococcus is apparently a much more fragile organism than the microbe of poliomyelitis.

It has been demonstrated that certain chemical disinfectants are effective against the virus in vitro; but in an investigation of the possible prophylactic value of chloramin-T, and dichloramin-T dissolved in chlorosane, after application of the virus into the nasal mucous membranes, Flexner and Amoss found that these chlorinated products exhibited no great protective action and are of doubtful value. In fact, the question has lately arisen as to whether antiseptic chemicals applied to the mucosa are not actually objectionable; for it appears that this membrane may sometimes function to prevent infection. According to the observations of Flexner and Amoss, certain animals are highly refractory to inoculation by way of the nares

with the virus of poliomyelitis, apparently in virtue of a power possessed by the membrane to destroy or otherwise render ineffective the virus that reaches it. Thus the latter will survive for an undetermined period on an ineffective, but for a relatively brief period of time on an effective, membrane.

It should be borne in mind, however, that this occasional property of the nasal mucosa appears to be distinct from any specific protective virtues that may appear in the blood. The poliomyelitic immune serum injected into the circulation is thought by Flexner and Amoss to meet the virus in the subarachnoid space. The low morbidity of poliomyelitis even during severe epidemics makes it seem probable that the insusceptibility of many persons is attained by some peculiar protection. If the normal nasal mucosa is part of the defense against the infection and serves to keep down the number of healthy and chronic carriers of the virus, it should be conserved in a healthy state. Local antiseptics are all too frequently merely chemical irritants; hence they should never be used indiscriminately—and evidently not in connection with poliomyelitis under the conditions just described.

VEGETABLE CARBOHYDRATES IN THE DIABETIC DIETARY

It has been pointed out by a number of writers¹ on the diabetic dietary that with the necessary exclusion of virtually all fruits and many vegetables because of their content of prohibited carbohydrate, the ration of the patients becomes much restricted, monotonous, and undesirably reduced in bulk. The diabetic craves the variety that is furnished by vegetable foods, so that the effort made to supplement his dietary with permissible additions will be fully justified. It is because of this that physicians much concerned with diabetics have begun to employ the so-called thrice-cooked or thrice-washed vegetables—products representing the residues, after repeated extraction, of such foods as carrots, cauliflower and cabbage, with water to remove the soluble carbohydrates.²

It has been debated whether vegetables thus freed from sugars and possibly other soluble carbohydrates still contain compounds that might yield sugar in the metabolism. Cellulose and, in some cases, starch are undoubtedly present. Published analyses by no means afford an accurate index, as the figures are commonly obtained by "difference," that is, by calculation of the residue of constituents not otherwise accounted for. When compounds potentially sugar-forming in the organism are fed to dogs rendered severely diabetic with phlorizin—so-called "total phlorizin diabetes"—the study of the urine makes it possible to ascertain how much, if any, of the intake can be converted to

1. Flexner, Simon, and Amoss, H. L.: Experiments on the Nasal Route of Infection in Poliomyelitis, *J. Exper. Med.* 31: 123 (Feb.) 1920.

sugar in the organism. From experiments of this type conducted at the Washington University School of Medicine at St. Louis, Olmsted³ has demonstrated that the usually employed green vegetables actually yield no more sugar in the body than the estimation of the starch and sugar preformed in them will account for. Thus, in the case of cabbage and cauliflower it does not exceed 5 and 3.4 per cent., respectively, while the same vegetables thrice cooked furnish no more than 0.5 and 0.8 per cent., respectively, of sugar. The dietitian may therefore continue the use and advocacy of this type of food when it is indicated, with the satisfaction of knowing that no unsuspected latent sources of sugar are being offered to the patient.

Only those who are obliged to deal practically with the needs of patients severely ill with diabetes can adequately appreciate the advantage of every innovation that may afford some culinary addition to their inevitably monotonous regimen. It is most unfortunate, therefore, that one should find a distinguished physiologist, in reviewing a study of thrice-cooked vegetables for diabetics, venturing to comment thus: "If all that is wanted is a pretense of food—a mere filling for the stomach—might one suggest some boiled filter-paper? This would mean a saving of the cook's time and of coals."⁴ Such uncalled for gibes bear the stamp of inexperience in the domain of dietotherapy.

THE PRECISE LOCATION OF PERICARDIAL EFFUSIONS

Clinicians are well aware that, unfortunately, the existence of pericarditis is often overlooked. Even when it is accompanied by pericardial effusion, the diagnosis is by no means always easy to make. The differentiation of the latter condition from cardiac dilatation occasionally presents great difficulties and is sometimes actually impossible. Paracentesis may fail to determine the presence or absence of fluid in the pericardial cavity. The reason for these uncertainties and the explanation for the errors in diagnosis sometimes made by even the most expert observers are found in part in the character of the evidence on which the clinician is forced to depend for his judgments. Although almost a hundred years have elapsed since Collin, Laënnec's assistant, demonstrated in 1824 the pericardial friction sound and interpreted its significance, this physical sign is not yet always so well defined as to be decisive. The determinations of the boundaries of dulness indicative of effusion involve possibilities of error, partly because of the personal equation of the observer and in part because of the shifting character of some exudates.

Even more fundamental than the difficulties just enumerated has been the lack of dependable informa-

tion regarding the anatomic relations of the heart to the pericardium when an effusion exists. Williamson,¹ who has lately called attention to these gaps in our knowledge, points out that some writers regard the heart as a heavy solid which sinks in an effusion to the lowest position in the pericardial sac. He correctly reminds us, however, that the fixation of the heart through its connections with the great vessels at its base and its attachment to the diaphragm by way of the inferior vena cava may prevent any "sinking" of the heart such as has been postulated. Nor is the heart to be regarded as capable of "floating" in an abundance of pericardial fluid. Where, then, does the latter distribute itself? Does it spread out laterally or vertically in its peculiarly limited confines? On the correct answer to such questions the interpretation of many physical signs elicited through the intact chest wall must depend. Furthermore, without accurate information of this sort, paracentesis of the pericardium may sometimes truly become, as Billroth characterized it in 1870, "a prostitution of surgical skill."²

Correspondingly welcome, therefore, are the elaborate investigations which Williamson¹ has conducted at the College of Medicine of the University of Illinois on the actual anatomic interrelations between the heart and pericardial effusions of varying magnitudes. He has arrived at the definite conclusion that the fluid accumulates first along the lower margin of the heart and about the apex, particularly on the diaphragmatic surface of the heart. With small effusions, this is the only place in which fluid accumulates with regularity. The result of the accumulation of the fluid in this position is to push down the left lobe of the liver. This feature is said to be sufficiently conspicuous to serve as an early diagnostic sign of effusion. The second place in which fluid accumulates, Williamson continues, is over the great vessels at the base. With small effusions it is occasionally present in sufficient amount to be detected by percussion. With medium sized effusions this layer is generally thick enough to be demonstrable by percussion, and this retrosternal dulness is an important diagnostic sign.

With respect to the debated anatomic relations, it is further of note that in a considerable number of Williamson's experiments on the cadaver the anterior surface of the heart, in spite of the exudate, remained in part uncovered by the fluid, so that a pericardial friction rub could readily exist. This persistence of the pericardial rub is to be anticipated in cases in which the heart is relatively large, so that it fills out the space between the vertebral column and the sternum.

When the volume of pericardial effusion is large, the chances of successful tapping are obviously good. Williamson introduced fluids in widely varying quan-

tities up to 655 c.c. From a survey of the observations made it appears that small amounts of fluid are most likely to be reached by puncture from a site either just outside the apex or in the chondroxyphoid angle. This study should be decidedly helpful in the future management of pericardial disease.

PROTECTION AGAINST CARBON MONOXID

It has become almost commonplace to observe that under the stress of war emergencies the scientific resources and investigative intelligence of our country were effectively requisitioned in many instances with a degree of success rarely approached under the less strenuous demands of peace time. Nowhere was this exemplified more strikingly than in the domain of chemistry. Chemical warfare assumed a new and unexpected significance from both the offensive and the defensive standpoint. The enormous development of American chemical industries incidentally created new possibilities in the production of medicinal chemicals as well as in the maintenance of such supplies, for which this country was formerly dependent on European continental sources. Furthermore, the menace of the poisonous war gases necessitated the discovery and invention of means of protection, some of which have found a valuable application in the dangers of every-day life.

Danger from various gases has long been recognized as a hygienic problem in several industries. This is true, for example, of carbon monoxid. Experts of the Chemical Warfare Service have asserted that the intentional use of this compound as a poisonous war gas is practically out of the question, primarily because of its relatively slight toxicity. They have pointed out that several minutes' inhalation of a mixture of one part in 100 parts of air is required to produce unconsciousness, while with a number of other toxic gases actually employed, such as phosgen, for instance, a similar length of exposure to one part in 100,000 parts of air, that is, to a mixture a thousand times more dilute, will prove fatal. Since it is difficult to set up the required concentrations of even the most toxic gases over significant areas in the open, it is evident that no possible degree of cheapness, accessibility, etc., could overcome so serious a handicap.¹

Nevertheless, defense against the danger of poisoning from carbon monoxid has been found necessary in both marine and land warfare. Defective ventilation in boiler rooms where products of incomplete combustion may escape, and in the neighborhood of explosions evolving large quantities of carbon monoxid, as well as in the relatively confined spaces of mining and sapping operations, calls for protection from the gas. Carbon monoxid is so inert chemically under ordinary

conditions that few substances react on it with the speed required in gas masks, through which human respiration must proceed rapidly. Most of the other poisonous gases encountered during the war were absorbed or neutralized by suitable compounds introduced into gas mask containers. In the case of carbon monoxid the problem proved to be singularly baffling until, thanks to the combined ingenuity of a number of American chemists, it was ascertained that in the presence of suitable catalysts carbon monoxid can be oxidized continuously by the oxygen of the air. The perfection of a suitable catalyst—"hopcalite," a mixture of oxides of manganese, copper, cobalt and silver—has lately been disclosed by permission of the Bureau of Mines and of the Chemical Warfare Service.

As a constituent of gas masks, this new product of the war-time chemistry promises to function effectively against any concentration of carbon monoxid. Its field of usefulness in peace time is likely to be found in plants for the manufacture of power and illuminating gas, and in the metallurgical industries, in which carbon monoxid is largely employed, with frequent casualties and even fatalities. The government experts indicate that in coal mining, in certain classes of copper mining, and wherever explosives are used in confined spaces, carbon monoxid is a serious menace responsible for the loss of many lives each year. Leaky flues, exhaust gases from explosion engines, improper ventilation where coal fires are employed, and the air to which firemen are exposed in burning buildings, all constantly take a not inconsiderable toll of lives. The therapeutics of poisoning from carbon monoxid has lately been put on a more rational basis, and now prophylactic hygiene has added further possibilities of averting danger from it.

Current Comment

THE MEDICAL AND SURGICAL HISTORY OF THE WAR

The Surgeon-General, with the approval of the Secretary of War, is asking for an appropriation, in the Sundry Civil Bill, for the publication of the medical and surgical history of the World War. In its projected form, this medical history will be more than an account of the rapid expansion and administrative achievements of the medical department; it will be a collective study of the many problems of hygiene, medicine and surgery which were involved in the efficient medical care of the nation's armies—in fact, a system of medicine and surgery based on the experience and observations of the physicians who guarded the health of our soldiers. The knowledge which was gained in hospitals and on the battlefield, and the vast amount of medical research carried on during the war, can be made of immediate value to the medical profession and the public only by prompt publication of the medical history. There can be no question of the

1. Lamb, A. B.; Bray, W. C., and Frazer, J. C. W.: The Removal of Carbon Monoxide from Air, *J. Indust. & Engin. Chem.* **12**: 213 (March) 1920.

merit of such a work; as a scientific record alone, the data will be of permanent value, irrespective of considerations regarding their utility as a source of information in future emergencies. The first volume of an unofficial history of the Canadian army medical corps appeared last year, steady progress has been made on the official British medical history, and the history of German participation in the war will be issued in nine volumes late in 1920; much of the material for the American history is already collected, and publication waits on the action of Congress. Nothing can be gained from procrastination and delay—the appropriation requested by the Surgeon-General should be allowed promptly. The medical and surgical history of the War of the Rebellion was delayed through twenty years. It is to be hoped that a similar fate does not await the publication of the Medical History of the World War. If Congress does not, within a short time, make the appropriation necessary for the printing of this available material, the failure will be tantamount to an order for its destruction. In a few years this material would be of archaic, but not of scientific, interest.

DETERIORATION OF STROPHANTHIN EMPHASIZES THE IMPORTANCE OF DETAILS

Factors that appear insignificant or of minor importance to the layman may play a surprisingly conspicuous part in the workings of science. Seemingly slight variations from the normal or the expected often alter the course of a reaction; that which is an infinitesimal quantity to the eyes of the untutored may become a highly potent portion in the hands of a trained worker. The latter may alter the functions of the human body by the use of less than a milligram or a hundredth of a grain of an active drug. Bacteria may be readily affected in their growth by variations in reaction that require special indicators for their easy detection. Physicians have learned that even a product as "pure" as is distilled water may need redistillation under special precautions to render it fit for therapeutic use. The foregoing instances are cited to illustrate the respect and attention which details deserve in paving the way to success in practice as well as in scientific medicine. A significant added example has just been furnished by Levy and Cullen¹ of the Hospital of the Rockefeller Institute for Medical Research in New York. Having observed wide variations of potency in the biologic assays of several lots of a commercial preparation of ouabain (g-strophanthin) furnished in ampules, they found that the sterilized solutions were decidedly alkaline in reaction, whereas freshly prepared aqueous solutions of the drug were neutral or slightly acid. This drug is readily rendered biologically inert by heating with alkalis. It was discovered that ordinary soft glass commonly used in making ampules employed in marketing sterile solutions for hypodermic or intravenous medication yields sufficient alkali on heating to change the reaction of distilled water—hence it is liable to decompose susceptible chemical

substances. Thus, some ampules may contain a drug in a concentration as low as 0.01 per cent., i. e., 0.5 mg. of drug in 5 c.c. The difficulty can readily be averted by the use of containers of hard glass. In the special case of crystalline strophanthin for clinical use, Levy and Cullen advise that it be dissolved in 0.02 molecular-gram of standard phosphate solution at p_H 7.0 and sterilized in hard glass ampules, under which conditions it has been kept undeteriorated for months. We reiterate the value of attention to details.

Association News

THE NEW ORLEANS SESSION

Special Party from St. Paul and Minneapolis

Dr. Harry F. Thompson, Forest City, Iowa, advises that he is organizing a party to go to New Orleans from St. Paul and Minneapolis, and will be pleased to correspond with any who desire to join the party.

Steamship Parties Called Off

Dr. Ira J. Haynes, Richmond, Va., writes that he has failed to secure a ship to carry a party from Baltimore to New Orleans to attend the annual session of the American Medical Association. Notwithstanding earnest efforts to charter such a boat, he was unable to obtain one. It has also been found impracticable to arrange for boats to carry parties to New Orleans down the Mississippi River.

Large Attendance Expected

Dr. A. E. Fossier, chairman of the Local Committee on Arrangements, reports that, judging from the large number of hotel reservations already made, the coming annual session of the Association is going to be a large one. Notwithstanding this, the Committee on Hotels is doing all in its power to avoid inconvenience or confusion for the Fellows who will be in New Orleans, and feels confident that comfortable accommodations will be available for all. It is urged, however, that hotel reservations be made promptly and in advance of going to New Orleans, by addressing the chairman of the Local Committee on Hotels, Dr. J. J. Wymer, 921 Canal Street.

Clinics Preceding and Following the Scientific Assembly of the American Medical Association

It is purposed to make available for these clinics all the hospitals affording sufficient facilities. The cooperation of the Charity Hospital of Louisiana, the Eye, Ear, Nose and Throat Hospital, Touro Infirmary, the Hotel Dieu, and the Presbyterian Hospital has been secured. These institutions are interested in placing their clinical material at the disposal of visiting physicians, and have entered into the spirit of the undertaking in the most cordial manner.

The clinics will be arranged for Thursday, Friday and Saturday of the week before the session, April 22, 23, 24; for Monday and Tuesday of the session week, April 26 and 27, and for the Saturday following, May 1.

In accordance with hospital customs in New Orleans, the operative clinics will be held in the forenoon, the nonoperative, in the afternoon. Daily a notice of the morrow's program will be multigraphed and posted in the registration booth, the hotels and the hospitals themselves. The program will give the number of visitors that can be accommodated in each clinic. All the institutions will offer instructive work each day, the programs running concurrently, so as to offer opportunities to as large a number of visitors as possible.

CHARITY HOSPITAL, Tulane Avenue between Howard and Magnolia, reached by Tulane Belt car on Canal Street, going from river. Operative clinics every forenoon, in Miles and Delgado buildings, accommo-

1. Levy, R. L., and Cullen, G. E.: Deterioration of Crystalline Strophanthin in Aqueous Solution, *J. Exper. Med.* 31: 267 (March) 1920.

dating, respectively, 525 and seventy-five spectators. Dispensary clinics every forenoon. Nonoperative (medical, dermatologic, obstetric) clinics in the afternoon, chiefly in the Miles Amphitheater (capacity, 500). *Surgery:* Drs. J. M. Batchelor, J. A. Dana, H. B. Gessner, F. A. Larue, E. D. Martin, R. Matas, F. W. Parham, John Smyth, M. J. Gelpi, C. Grenes Cole, J. E. Landry, Henry Leidenheimer, C. W. Allen, U. Maes, W. M. Perkins, A. C. King, M. Bradburn, W. P. Bradburn, A. Duncan, J. F. Points, John Lindner, A. A. Keller and E. J. Richard. *Medicine:* Drs. John B. Elliott, Jr., J. A. Bel, Benjamin Ledbetter, J. T. Halsey, G. Farrar Patton, Edward Moss, J. B. Guthrie, I. I. Lemann, J. A. Storck, Otto Lerch, Hamilton P. Jones, L. L. Cazenavette, Wallace Durel, Harry Daspit, A. E. Fossier, O. W. Bethea, J. L. Lewis, R. Lyons, Chaille Jamison and J. C. Cole. *Gynecology and Obstetrics:* Drs. S. M. D. Clark, William Kohlmann, Paul Michinard, C. Jeff Miller, H. S. Cocram, W. W. Leake, H. W. Kostmayer, J. W. Newman, E. H. Walet, P. B. Salatch, C. P. Holderith, E. D. Friedrichs, J. F. Dicks, E. L. King, C. A. M. Dorrestein and C. P. Brown. *Orthopedics:* Drs. E. D. Fenner, John F. Oechsner, Paul A. McIlhenny, Solon Wilson, James T. Nix, Jr., and Joseph Levy. *Urology:* Drs. S. P. Delaup, Joseph Ilume, A. Nelken, Paul Gelpi, Henry Walther, P. J. Kahle and H. Lindner. *Ophthalmology:* Drs. M. Feingold, T. J. Dimitry, A. L. Whitmire, V. Smith, Henry Blum and A. R. Crebbin. *Diseases of the Ear, Nose and Throat:* Drs. Homer Dupuy, S. M. Blackshear, W. T. Patton, J. A. Estopinol, L. de Poorter and William Scheppegrell (hay-fever clinic). *Pediatrics:* Drs. C. A. Borey, L. R. De Buys, C. J. Bloom, John Signorelli, R. A. Strong, R. Crawford and G. J. de Reyna. *Dermatology:* Drs. Isadore Dyer, H. E. Ménage and J. N. Roussel. *Radiology:* Dr. G. B. Harney. *Pathology:* Dr. C. W. Duval.

EYE, EAR, NOSE AND THROAT HOSPITAL, Tulane Avenue, corner of Elk Place, five squares from Charity Hospital, reached by Tulane Belt car on Canal St., going from the river. Dispensary and operative clinics, each, nose and throat, in the morning; eye, in the afternoon. Amphitheater seats fifty. *Eye:* Drs. Henry Dickson Bruus, E. A. Robin, C. A. Bahn, W. R. Buffington and E. McCarthy. *Ear, Nose and Throat:* Drs. R. C. Lynch, John T. Crebbin, George Taquine and J. D. Martin.

TOURO INFIRMARY, Prytania, between Aline and Foucher, reached by Prytania car at Canal and Camp, or St. Charles Belt. Dispensary in the forenoon. Operative clinics every forenoon; six rooms accommodate sixty. Medical clinics in the afternoon; accommodations for 200. *Surgery:* Drs. R. Matas, F. W. Parham, E. D. Martin, C. Jeff Miller, S. M. D. Clark, C. W. Allen, A. Nelken, H. B. Gessner, U. Maes, L. H. Landry, R. E. Stone and Isidore Cohn. *Obstetrics and Gynecology:* Drs. William Kohlmann, J. W. Newman, J. Barnett, J. G. Hirsch, Joseph Conn and C. A. M. Dorrestein. *Orthopedics:* Drs. E. S. Hatch, J. T. O'Farrall and L. C. Spencer. *Eye:* Drs. M. Feingold, Henry Blum and A. R. Crebbin. *Ear, Nose and Throat:* Drs. C. J. Landfried, R. C. Lynch, J. P. Leake, A. I. Weil, S. M. Blackshear and H. L. Kearney. *Medicine:* Drs. I. I. Lemann, L. D. DeBuys, S. K. Simon, R. M. Van Wart, C. L. Eshleman, R. Lyons, J. M. Bamber, J. C. Cole, O. F. Ernst, A. L. Levine, C. J. Bloom, C. S. Holbrook and B. R. Heninger. *Radiology:* Drs. E. C. Samuel and E. R. Bowic. *Dermatology:* Drs. J. N. Roussel and R. A. Oriol. *Pathology:* Dr. J. A. Lanford.

HOTEL DIEU, Tulane Avenue, corner of Johnson, reached by Tulane Belt car on Canal Street, going from the river. Operative clinics every forenoon; five rooms accommodate a total of twenty-five. Drs. M. Souchon, J. A. Dania, J. T. Nix, Jr., Louis Levy, Homer Dupuy, J. J. Ryan, H. W. Kostmayer and Maurice Gelpi. *Radiology:* Dr. L. A. Fortier. *Pathology:* Dr. M. Couret.

PRESBYTERIAN HOSPITAL, Carondelet Street, between Julia and Girod, reached by Peters Avenue and Laurel Street cars at Carondelet and Canal. Operative clinics in the forenoon; four rooms accommodate a total of forty. Demonstration of pathologic specimens and roentgenograms in the forenoon. *Surgery, including Special Senses:* Drs. J. P. O'Kelley, W. D. Phillips, C. Grenes Cole, Roy Harrison, A. O. Hoeft, Joseph Hume, J. R. Ilume, John Smyth, D. L. Watson, M. P. Boebinger, F. A. Overbay and H. S. Cocram. *Internal Medicine:* Drs. J. L. Lewis, Chaille Jamison and F. Lamothe. *Pathology:* Dr. William H. Harris. *Radiology:* Dr. Adolph Henriques.

Welfare of the Blind.—The British Department Committee on the Welfare of the Blind, which reported in July, 1917, recommended the establishment in the Local Government Board of a special department whose functions should be the general care and supervision of the blind and the appointment of an advisory committee of persons associated with the care of the blind. Its first report (for the period ended March 31, 1919) has been published by the ministry of health. A register formed on the replies thereto shows a total of 25,840 blind persons in England and Wales. Inquiry was made into the work of the blind, and it was found that the employable group (11,895) is the largest, being 46 per cent. of the total unenumerated. Of blind persons in occupations most are engaged in basket and cane work; there are relatively few in outdoor occupations. A large number of blind children are not attending school, and of these 40.6 per cent. were returned as mentally defective. A table of the age of onset of blindness shows that 21.4 per cent. were blinded within the first year of life, the majority of them within the first month. After the first year the incidence is, roughly, 10 per cent. for each decade up to 70 years.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Personal.—Dr. Charles A. Mohr, Mobile, health officer of Mobile County, has resigned on account of his duties as health officer of Mobile.—Dr. Paul P. Salter, Montgomery, director of the state laboratories for several years, has resigned and will practice in Eufaula.—Dr. Frederick K. Reynolds, Montgomery, assistant state health officer, has resigned and will practice in Montgomery.

ILLINOIS

Smallpox in Evanston.—Two cases of smallpox, the first to be reported in Evanston for five years, were discovered March 23. Both patients were taken to the Chicago Isolation Hospital.

Asks New Trial.—Motion for a new trial in the case of Dr. George W. Alverson, Sciota, convicted of the murder of Lawrence Clugston, were filed with the circuit court of McDonough County, February 28.

Branch Association Organized.—The Belleville Branch of the St. Clair County Medical Association was organized at Belleville, March 2. The membership in the branch will include not only physicians of Belleville but also those from the central and eastern parts of St. Clair County. Dr. Buenaventura H. Portuondo was elected president; Dr. William L. Hanson, secretary, and Dr. Delmar R. Duey, treasurer, all of Belleville.

The Venereal Disease Plague.—Certain communities in Illinois and on the Indiana border, notorious as breeding places of venereal diseases, will be cleaned out by the attorney general, county commissioners and municipal health departments. This decision was arrived at, March 25, after a lengthy conference called by Pres. Peter Reinberg of the Cook County board, and suggested by Dr. George G. Taylor, Springfield, chief of the division of social hygiene of the Illinois department of public health. Every person known to be infected will be taken to a clinic or hospital and treated until cured or safe.

State Dentists Meet.—The fifty-sixth annual meeting of the Illinois State Dental Society was held in Chicago, March 22 to 25, with about 4,000 in attendance. The chief topics of discussion were the importance of dental work in public schools, the antisugar campaign, the gospel of the clean mouth and the relation of systemic diseases to infected teeth. March 23 was devoted to a clinic by the Chicago Dental Society, and in the evening a testimonial banquet was given to Dr. Thomas Lewis Gilmer, dean of the profession in Chicago. Dr. J. T. Luthringer, Peoria, was elected president; Dr. Frederick B. Noyes, Chicago, president elect, and Dr. C. W. Coltran, Chicago, vice president.

Chicago

Research Club Meeting.—At a meeting of the Medical Research Club of the University of Illinois, held Thursday, March 25, in the college of medicine, Prof. A. H. Clarke, school of pharmacy, discussed "The Work of the Council of Pharmacy and Chemistry of the American Medical Association," and Paul N. Leech of the Laboratory of the American Medical Association, spoke on "Some of the Council's Problems with Therapeutic Agents." The faculty of the college of medicine passed a resolution commending the aims and work of the Council.

Public School Athletic League Formed.—To make Chicago's 400,000 schoolchildren the healthiest schoolchildren in America is the purpose of the Chicago Public School Athletic League, an organization recently authorized at the instigation of the mayor and approved and supported by city and park officials, the board of education, members of civic organizations and principals of the high and elementary schools of Chicago. It is proposed to initiate efficient coaching and training, together with expert direction along the special lines of activity for which the individual boy is best fitted. This cannot fail to raise the standard of health, character and physical fitness.

Honored for War Service.—Dr. Gustavus M. Blech, who as lieutenant-colonel, M. C., U. S. Army, commanded Base Hospital No. 208, near Bordeaux, the largest base hospital in France, having a capacity of more than 7,000 patients, has received through the Adjutant-General of the Army, a citation certificate of the Order of University Palms with the grade of Officier de l'Instruction Publique—gold palms, awarded to him by the French government for services rendered to French officers and the government at the University of Bordeaux. —Dr. Maurice L. Goodkind has received, through the Adjutant-General of the army, a citation certificate of the Order of the University Palms of the grade officer of the Academy—silver palm, awarded by the French government Nov. 18, 1919, for services as chief of the medical service of Base Hospital No. 53, Langres sur Marne, France.

Society Meetings.—At the meeting of the Chicago Medical Society, March 31, Dr. Edward A. Foley, assistant superintendent of the Chicago State Hospital, discussed the "Difficulties Encountered in Dealing with Mental and Delinquent Cases," with special reference to interference by newspapers, lawyers, physicians and the general public in endeavoring to secure releases from institutions of such cases; Dr. William O. Krohn, spoke on "The Malingering as a Medical and Medicolegal Problem," and Dr. Daniel N. Eisendrath gave a report on "Recent Progress in Kidney and Ureteral Surgery." —At the meeting of the Society of Medical History of Chicago, held at the City Club, March 30, Dr. Morris Fishbein presented a paper on "Physicians' Fees;" Dr. Clarence A. Earle, Desplaines, one on "Pioneer Physicians of the Desplaines Valley," and Dr. Benjamin F. Uran, Kankakee, one on "The Names and Early History of Physicians of Kankakee County."

KANSAS

Personal.—Dr. Alva E. Billings, Topeka, has been appointed medical director of the Security Benefit Association, succeeding Dr. Oscar L. Peak, deceased. —Dr. A. L. Shelton, Hutchinson, the first American medical missionary to enter Tibet, who was captured by Chinese bandits, January 4, near Laoyakwan, has been released.

School for Health Officers.—Dr. Eugene R. Kelley, Boston, health commissioner of Boston, and Mazyck P. Ravenel, Columbia, professor of preventive medicine in the University of Missouri, have been secured as instructors for the school for public health officers which is to be held in Rosedale, May 10 to 15, inclusive. An officer of the U. S. Public Health Service will also be detailed for this work. The mornings will be devoted to clinics at the Bell Memorial Hospital, Rosedale, and the afternoons will be taken up in general public health work.

KENTUCKY

Personal.—Dr. L. A. Megler, Louisville, has been appointed school medical inspector, succeeding Dr. Lester A. Crutcher, resigned to become registrar of vital statistics for Jefferson County in place of Dr. William E. Grant, deceased. —Dr. John Hamilton, Owensboro, has been selected health officer of Daviess County.

Recent Legislation.—The legislature of Kentucky has enacted the following bills affecting the medical profession and public health: senate bill No. 220 provides for the establishment of a state board of health of nine members all legally qualified practitioners, except one, a registered pharmacist, eight of whom shall be appointed by the governor and the ninth who shall be secretary and state health officer, elected by the board: one member a homeopath, one eclectic and one osteopath, one a registered pharmacist, and all the other members physicians, all to be appointed by the governor from a list of three names for each vacancy furnished respectively by the state society or association of such physicians, or cities and boards as are entitled to a member, and the pharmacist from a similar list of three names submitted by the Kentucky Pharmaceutical Association. The president, secretary and members of the board and other officers and employees are to receive annual salaries to be fixed by the state board of health, to be paid as salaries and expenses as now paid. The other members of the board shall receive no per diem compensation for their services, except when sent by the board on special duties and when preparing and conducting examinations. A fund is created for the purpose of extending state aid to counties or districts establishing and maintaining county or district departments of health and authorizing the auditor to draw his warrant in favor of the state board of health, for the use of each county which has established such a county or district health department

for the sum of \$2,500 annually. Senate bill No. 408 gives immediate possession of Hazelwood Sanatorium for a state tuberculosis sanatorium. Senate bill No. 29 is an advanced housing bill. The budget commission has increased the appropriation of the state board from \$75,000 to \$165,000 per annum. —A joint resolution was passed and signed by the governor thanking the U. S. Public Health Service for the effective work done by Surg. John McMullen in trachoma eradication, and an appropriation of \$13,700 was made for a traveling clinic to work in conjunction with Dr. McMullen.

MARYLAND

To Guard Against Smallpox.—To prevent persons from New Orleans race tracks bringing smallpox into Baltimore city or the state, deputies from the state department of health are meeting every race horse train coming here for the spring racing meets. Dr. John S. Fulton, Baltimore, secretary of the board, has been notified by New Orleans health officials that a recent epidemic of the disease in that city claimed many victims among stable boys and other track employees. In spite of the vigilance of Louisiana officials, it is feared that some one suffering from the disease will slip out of the state.

For Care of Soldiers, Sailors and Marines.—The U. S. Public Health Service has entered into an agreement with the state lunacy commission and the board of managers of the Spring Grove State Hospital at Catonsville to care for soldiers, sailors and marines of Maryland suffering from mental disorders in the Arthur D. Foster Psychopathic Clinic, a separate building recently completed. The clinic will be equipped and ready for the reception of patients about May 1, and will afford accommodation for about 100 cases. The U. S. Public Health Service has agreed to furnish a clinical director, a graduate nurse to take charge of the nursing, and an occupational aide.

MICHIGAN

Health Bulletin.—The department of health of Ishpeming began in January the issuing of a monthly bulletin known as the *Ishpeming Health News*, edited by the health officer, Dr. David Littlejohn. The periodical is distributed without charge to the people of the community and contains much valuable information regarding public health.

MINNESOTA

Personal.—Dr. Harry M. E. Lowell of the Mayo Clinic, Rochester, has been appointed superintendent of the Mercy Hospital, Hamilton, Ohio. —Dr. John S. Abbott has succeeded Dr. Robert I. Hubert, resigned, as deputy health officer of St. Paul. —Dr. Herbert G. Lampson, Duluth, has been appointed physician of St. Louis County, succeeding Dr. Daniel F. V. Pennie. —Miss Linda James, St. Paul, has been appointed field secretary of the Minnesota Public Health Association.

Society Organized.—Hennepin County Tuberculosis Association has been organized to succeed the antituberculosis committee of the associated charities. Dr. Henry L. Ulrich, Minneapolis, was elected president; Drs. John W. Bell, Minneapolis, G. D. Health and John G. Gross, Minneapolis, honorary members, and Dr. Hugh C. Arey, Excelsior; Albert J. Chesley, Minneapolis; Henry W. Cook, Minneapolis; Charles E. Dutton, Minneapolis; Charles D. Harrington, Minneapolis; Frank H. Hacking, Minneapolis; Walter J. Marcle, Minneapolis; Ernest S. Mariette, Glen Lake; Harold E. Robertson, Minneapolis; J. Sundwall, Henry L. Ulrich, Minneapolis, and Frederick W. Wittich, Minneapolis, directors.

NEW JERSEY

Personal.—Dr. Walter R. Elliott, West Collingswood, has been elected president of the new Memorial National Bank, Collingswood. —Dr. Benjamin Van Doren Hedges, Plainfield, has been elected secretary of the city board of education. —Dr. Arthur L. Smith, New Brunswick, has been reelected president of the board of education. —Dr. Louis Schneider, Newark, has been appointed a member of the board of managers of the Contagious Disease Hospital, Soho. —Dr. John Miller, Netcong, was caught under his overturned sleigh recently and his right leg was fractured.

NEW YORK

Merritt H. Cash Prize.—The Merritt H. Cash prize of \$100 provided for by a fund administered by the Medical Society of the State of New York was awarded this year to Dr.

Herman B. Sheffield for an essay on "The Present Status of Poliomyelitis."

State Society Raises Dues.—The Medical Society of the State of New York at its recent meeting amended its by-laws to provide for an increase in the annual per capita dues from \$3 to \$5. Resolutions were passed instructing the delegates to the meeting of the American Medical Association to submit resolutions opposing compulsory health insurance to the House of Delegates, and to support such resolutions in every possible way.

State Society Elects.—At the annual meeting of the Medical Society of the State of New York, held in New York City, March 22 to 25, 1920, the following officers were elected: president, Dr. John Richard Kevin, Brooklyn; vice presidents, Dr. William Meddaugh Dunning, New York City, Dr. Wesley T. Mulligan, Rochester, and Dr. William H. Purdy, White Plains; secretary, Dr. Edward Livingston Hunt, New York City; assistant secretary, Dr. Charles Gordon Heyd, New York City; treasurer, Dr. Harlow Brooks, New York City; assistant treasurer, Dr. Seth M. Milliken, New York City; speaker of the house of delegates, Dr. Edward Eliot Harris of New York City, and vice speaker, Dr. Dwight H. Murray, Syracuse.

New York City

Physicians' Home.—A number of well known physicians of New York have been granted a charter to establish a Physicians' Home in which medical men who have become incapacitated for work through illness or old age might find an asylum. The president of the movement is Dr. Robert T. Morris; the secretary is Dr. Silas F. Hallock.

New York University Doctors Organize.—Graduates of the New York University and Bellevue Hospital Medical College met March 23 and organized an alumni association, electing the following officers: president, Dr. Robert J. Carlisle; vice president, Dr. Robert J. Wilson; secretary, Dr. Cornelius J. Tyson, and treasurer, Dr. Godfrey R. Pisek.

The Post-Graduate Medical School Fund.—Though the campaign to raise a \$2,000,000 endowment fund for the Post-Graduate Medical School and Hospital does not begin until March 30, a number of substantial preliminary gifts have been received. One of these is \$50,000 from James C. Brady. Dr. James F. McKernon is chairman of the committee directing the campaign.

New York Physicians Aid Vienna Physicians.—Physicians and surgeons of this city have contributed \$10,000 to supply food to the members of the medical profession in Vienna. The money has been turned over to the American Relief Administration for conversion into food drafts. Dr. Linsly R. Williams in Paris will go to Vienna to arrange for the food distribution.

OHIO

Building for Public Health Bodies.—The Toledo Academy of Medicine is planning to purchase the Hurd Democratic Club House which has been offered to it for \$42,500. Physicians have already subscribed \$20,000 toward the purchase of the property. It is believed that the building will be able to house all the public health organizations of the city, including the visiting nurse association and a medical library.

Must Serve Sentence.—Dr. Raphael W. Miller, convicted in the Cincinnati Municipal Court several years ago on the charge of violation of the narcotic law, has, it is said, lost his appeal in the court of appeals, and will have to serve three months in jail and pay a fine of \$500. The conviction, it is said, was the result of a charge that he and a druggist had supplied a woman with narcotics. The druggist was acquitted in the municipal court.

Personal.—Dr. Milo Wilson, Gallipolis, has been transferred from the Ohio Hospital for Epileptics, Gallipolis, to Holzer Hospital, Gallipolis. Dr. Edwin J. Rose, Gallipolis, has been appointed a member of the staff of the Ohio Hospital for Epileptics, Gallipolis. Dr. William A. McIntosh, Oberlin, has been appointed health commissioner of Lorain County. Dr. Philip H. Dorger, city bacteriologist of Cincinnati, has resigned. Dr. Foy C. Payne, Dayton, has been appointed pathologist; Dr. Robert C. Austin, Dayton, orthopedic surgeon, and R. M. Cope, oral surgeon, to the Stillwater Sanitarium, Dayton. Dr. Rush R. Richison, Springfield, has been appointed health commissioner of Clark County. Dr. Carl W. Hoopes, Marysville, has been selected as health commissioner of Union County. Dr. Daniel E. Rausch, Stone Creek, has been elected president of the Tuscarawas County Board of Health.

PENNSYLVANIA

License Revoked.—The Board of Medical Education and Licensure is said to have revoked the license to practice medicine in Pennsylvania of Dr. Ellsworth J. Trader, Pittsburgh, who is now serving a sentence in the federal prison, Atlanta, Ga., for illegal writing of prescriptions for narcotics.

Medical Legislative Conference of Pennsylvania.—March 13, 1920, representatives of the Eclectic Medical Society, the Homeopathic Medical Society and the Medical Society of the State of Pennsylvania met in Philadelphia and organized the Medical Legislative Conference of Pennsylvania. Dr. George A. Knowles was elected chairman, and Dr. Edward A. Krusen, Norristown, secretary-treasurer.

Adams County Hospital.—The Annie M. Warner County Hospital, Gettysburg, a new hospital building accommodating forty patients, and 6 cases of land have been presented by John M. Warner to a board of managers drawn from every part of the county. The managers have announced the purchase of 14 additional acres of land. A campaign for \$100,000 endowment launched last fall will be pressed for early completion.

Health Commission Appointed.—The new state health insurance commission recently appointed by the governor has elected William T. Ramsey, mayor of Chester, chairman; Representative Theodore Campbell, treasurer, and Dr. Francis D. Patterson, Harrisburg, secretary. The commission seeks the cooperation of all physicians, employees, employers, and all other persons interested, in order that it may secure the necessary facts for making a report to submit to the governor which can be made the basis of legislation.

Philadelphia

For Control of City Dumps.—Rigid control of the dumps in the south Philadelphia "neck" district is being planned by Director Furbush of the department of public works as a part of a campaign for the correction of insanitary conditions in the southern part of the city.

Housing Association Annual Meeting.—The annual meeting of the Philadelphia Housing Association was held at the City Club, March 26. According to the annual report of conditions, only 18 per cent. of the 7,662 houses complained about have been corrected and the insanitary area of Philadelphia is increasing.

Personal.—Dr. Robert N. Kelly has been appointed surgeon of the Nautical School, Annapolis. Dr. Dorothy Child has resigned as director of the bureau of child health in the state department of health to take effect April 1. Dr. Karl Schaffle has resigned as head of the tuberculosis division of the state department of health. Dr. Isaac A. Abt, Chicago, delivered an address before the Pediatric Society of Western Pennsylvania at Pittsburgh, March 29.

City Bath Houses Insanitary.—Dr. Hunter Blair Spencer, chief physician of the bureau of corrections and charities, has been making an inspection of the twenty-three public bath houses situated in different sections of the city and has found that some are in an insanitary and dangerous condition and unfit for use. The arrangements of the dressing rooms and shower baths in many of the buildings are dangerous to health, the shower baths draining into the pools.

SOUTH CAROLINA

Personal.—Dr. George McF. Mood has been reelected city bacteriologist of Charleston. Dr. John G. McMaster, Florence, suffered serious burns of the face and hands, March 3, when he attempted to throw a burning oil stove from his office window.

New Medical Bill.—Governor Cooper on March 10 signed the new medical bill which was drawn by the state medical society and recently passed by the legislature. This bill requires all chiropractors, osteopaths, homeopaths and other healers to submit to examination before the state board of medical examiners.

Medical School Gets Larger Income.—The Medical College of the State of South Carolina secured an appropriation of \$71,000 from the state for maintenance, as compared with \$49,500 last year. An additional appropriation of \$60,000 was made for a physiology building and equipment. The sum of \$10,000 was received from the sale of the old medical building.

TENNESSEE

Roentgen-Ray Machine Given Hospital.—A citizen of Memphis who desires to remain anonymous has given a roentgen-ray machine, valued at \$1,000, to the Crippled Children's Hospital.

State Association Meeting.—The eighty-seventh annual meeting of the Tennessee Medical Association will be held in Chattanooga, April 6 to 8, under the presidency of Dr. Andrew F. Richards, Sparta. The association will be the guest of the Chattanooga Academy of Medicine.

Personal.—Dr. Cummings Harris has been appointed secretary of the Memphis Health Department, succeeding Dr. Newman Taylor.—Dr. Evander M. Sanders, Nashville, has been appointed surgeon-general on the staff of the governor of Tennessee, succeeding Dr. Mathew C. McGannon, deceased.

TEXAS

New Officers.—At the annual meeting of the Brazos County Medical Association held in Bryan, the following officers were elected: president, Dr. William B. Cline; vice president, Dr. Claude A. Searcy, and secretary-treasurer, Dr. Lonnie O. Wilkerson, all of Bryan.

New Home for Medical Society.—The Bexar County Medical Association has completed a negotiation for the purchase of the Julius Appler property, San Antonio, for \$20,000. An auditorium will be arranged on the second floor and the library and pathologic museum will be maintained on the first floor of the building.

Chiropractor Jailed.—Byron S. Black, a chiropractor of El Paso, is said to be confined in the county jail serving a sentence of twenty days on two charges of practicing medicine without a license. On the first charge, he is said to have been fined \$250 and sentenced to ten days' imprisonment and in the second case fined \$50 and sentenced to a similar period in prison.

Medical Board Election.—At the annual meeting of the Texas State Board of Medical Examiners held at Dallas, March 16, the board was reorganized with the election of the following officers: president, D. S. Harris, D.O., Dallas; vice president, Dr. Robert Y. Lacy, Pittsburg, and secretary, Dr. Thomas J. Crowe, Dallas. The next meeting of the board will be held in Galveston, June 21 to 23.

VIRGINIA

Health Almanac Reappears.—The *Virginia Health Almanac*, after an absence of several years, due to the pressure of war conditions, has made its reappearance.

Appropriation for Orthopedic Hospital.—Among the measures passed by the Virginia legislature, March 13, was one appropriating \$30,000 to the state board of health for the purpose of building an orthopedic hospital for the treatment of crippled and deformed children.

Reduction of Motherhood Casualties.—Educational work conducted by the bureau of vital statistics of the state board of health saved the lives of 164 mothers in the state in 1919, as compared with the casualty list of motherhood in 1917. In 1913, 408 Virginia mothers died at childbirth; in 1914, 487; in 1915, 469; in 1916, 467, and in 1917, 497.

WISCONSIN

Sanatorium Grounds Enlarged.—The site of the Tri-County Tuberculosis Sanitarium, Washburn, has been enlarged by the donation by F. V. Holston of Bayfield, of a tract of land to be used for park purposes, and to be known as the Lelia A. Holston Memorial Park.

Fox River Physicians Elect Officers.—At the annual meeting of the Fox River Medical Society held in Green Bay, March 4, the following officers were elected: president, Dr. William H. Bartran, Green Bay; vice presidents, Dr. Emile G. Nadeau, Green Bay, and Frank J. Wochos, Kewaunee, and secretary-treasurer, Dr. Robert L. Cowles, Green Bay.

Personal.—Dr. Harry Cohn, Wauwatosa, head of the Milwaukee County Free Medical Dispensary, has resigned and has been succeeded by Dr. Harry W. Sargeant, Wauwatosa.—Dr. Charles A. Lothrop, Ripon, has been elected surgeon to the Wisconsin Veteran's Home, succeeding the late Major Albert E. McCallin.—Dr. Henry Hannum, Bayfield, who has been under treatment at a hospital in Ashland for several months on account of a broken hip, has left for the home of his son in Muskegon.

CANADA

Dominion Physicians to Meet.—The fifty-first annual meeting of the Canadian Medical Association will be held in Vancouver, B. C., June 22 to 25, under the presidency of Dr. Simeon E. Grondin, Quebec. At the same time the Canadian Public Health Association, Canadian Association for the Prevention of Tuberculosis, Canadian Committee on Mental Hygiene, National Committee for Combating Venereal Diseases, and British Columbia Hospital Association will hold their annual meetings.

Personal.—Dr. W. M. Douglas Cruickshank, Hamilton, Ont., formerly Captain, C. A. M. C., and house surgeon in the New York Lying-In Hospital, and resident gynecologist to the Woman's Hospital, New York City, is now professor of obstetrics and gynecology in the Syrian Protestant College, Beirut, Syria.—Dr. John Stewart, Halifax, has been appointed dean of the faculty of medicine of Dalhousie University.—Dr. Edward C. Arthur, Nelson, has been appointed traveling medical officer for the province of British Columbia.—Dr. Frederick W. Marlow, Toronto, has been elected chairman of the special committee in Toronto on venereal diseases.

GENERAL

General Blue Goes Abroad.—Dr. Rupert Blue, formerly Surgeon-General, U. S. Public Health Service, left New York, March 27, for Southampton on official business.

Western Electrotherapists to Meet.—The annual meeting of the Western Electro-Therapeutic Association will be held in Kansas City, Mo., May 27 and 28, under the presidency of Dr. Burton B. Grover, Colorado Springs, Colo.

Grant for Research Work.—The American Pharmaceutical Association announces that it has available a sum amounting to about \$450 which will be expended after Oct. 1, 1920, for the encouragement of research either in full or in such fractions as in the judgment of the research committee of the association will produce the greatest good to American pharmaceutical research. Investigators desiring financial aid in the work should communicate with H. V. Arny, chairman of the American Pharmaceutical Association, Research Committee, 115 West Sixty-Eighth Street, New York City, before May 1, giving their record and outlining the particular line of work for which the grant is required. The awards will be made at the meeting of the American Pharmaceutical Association in Washington, May 3 to 8.

Honest Merchandise Act Introduced.—Congressman Rogers of Massachusetts has introduced in the House a bill to protect the public against fraud by prohibiting the manufacture, sale or transportation of misbranded, misrepresented or falsely described articles in interstate commerce. The measure is known as the Honest Merchandise Act. It applies to drugs and any articles of general manufacture. The bill places a penalty on misbranding any article offered for sale and transmitted in interstate commerce. It requires the contents of each article in package form to show on its outside the terms of weight, measure and quality; it requires that the examination of specimens shall be made in the Bureau of Standards at Washington, D. C., for the purpose of ascertaining whether such articles are described within the meaning of the bill and places a penalty of \$1,000 or imprisonment for one year on offenders.

Society for Visual Education Incorporated.—Recently, a group of educators, most of them prominent in university circles, have organized a society for visual education, to promote the cause of visual education in general, and the use of motion pictures in particular. It is stated that the society does not propose to displace textbooks, models, maps or any other educational means, but to supplement them and to make them more available. The society also proposes to publish a monthly periodical called *Visual Education*, the first number of which has been issued. The personnel of the organization, in addition to the officers, Rollin D. Salisbury, University of Chicago, president; F. R. Moulton, University of Chicago, secretary, and H. L. Clark, Utilities Development Corporation, vice president and general manager, includes a board of directors, representing most of the universities, a large general advisory board and special committees in all the various sciences and educational departments. The address of the organization is 327 South LaSalle Street, Chicago.

Influenza Epidemic Over.—The sharp decline in the morbidity and mortality rates from influenza and pneumonia for the week ending March 13 indicates that the epidemic is

practically over. The epidemic reached its height in the week ending February 14, when 267,643 cases were reported from forty-one states and the excess annual death rate as compared with the average for the period from 1910 to 1916 was 1,319. The weekly ratios of excess annual death rate for the seven weeks ending Jan. 17 to March 13, 1920, respectively, as compared to corresponding weeks ending Sept. 28 to Nov. 23, 1918, respectively, were 0.086, 0.232, 0.311, 0.282, 0.293, 0.277, 0.260, 0.243 and 0.184.—The Bureau of the Census has just issued a special report on the mortality in Indiana, Kansas and Philadelphia for the period, Sept. 1 to Dec. 31, 1918. It is estimated that 445,000 deaths from the epidemic of influenza occurred in the United States in that period. According to age periods, the highest rates occurred in the age period from 30 to 34 years, with the period 25 to 29 years second. Of all of the deaths tabulated, more than half occurred between the period of 20 to 40, although this age group represents only 33 per cent. of the total population concerned. Particularly important are the data relative to stillbirths. The large number of stillbirths occurring clearly points to the epidemic as the cause, and shows definitely the serious effect of the epidemic on pregnant women.

Bequests and Donations.—The following bequests and donations have recently been announced:

Bryn Mawr, Pa., Hospital, Maternity Ward Building Fund, \$5,307.50, the proceeds of the Bryn Mawr horse show.

Elizabeth, N. J., General Hospital, \$2,000, by the will of William T. Day, Newark.

Memorial Hospital, Morristown, N. J., two plots of land valued at \$20,000 and \$25,000, donated by Mrs. Marcellus Hartley Dodge.

Somerset, N. J., Hospital, one-half interest in the home and property of J. C. Kenyon, Raritan.

Lewistown, Pa., Hospital, \$1,500, by the will of Harriet Thomas Kurtz.

University of Pennsylvania, Philadelphia, \$50,000 for the establishment of a chair of gynecology, by the estate of Dr. William C. Goodell.

Methodist Episcopal Hospital, Philadelphia, \$25,000, the income to be used for maintenance of five free beds, by the will of Thomas Bradley.

Ohio-Miami Medical College, University of Cincinnati, a donation of \$100,000 to establish a department of preventive medicine in memory of the late Dr. Christian R. Holmes, by Mrs. Charles Fleischmann.

Ohio-Miami Medical College, University of Cincinnati, a donation of \$3,000 toward the equipment of a laboratory in the department of preventive medicine by Mrs. Christian R. Holmes, in memory of her husband.

St. Luke's Hospital, New York City, and American Red Cross, equal shares of the residuary estate of \$2,423,784, by the will of James C. Scrymser.

Henry Street Settlement, New York City, a donation of \$50,000, by Misses Alice D. and Irene Lewisohn.

FOREIGN

Personal.—Dr. Francisco Oliver, professor in the University of Zaragoza, Spain, has arrived in this country where he has been sent by the government of Spain to make special studies on methods to combat tuberculosis. Dr. Oliver was recently in England on a similar mission. He expects to stay in the United States until July.

Plague in Netherlands India.—Our Netherlands exchanges cite figures which show a flaring up of the plague in the Dutch East Indies. Since the serious epidemic of several years ago there have been only a few cases of plague here and there in the islands every week but in January there was a total of 1,746 cases in eight different places, all fatal.

Deaths in the Profession Abroad.—Dr. B. Giesker, dean of the physicians of Zurich, Switzerland, aged 79.—Dr. A. Zoppi of Venice, a prominent surgeon and orthopedist.—Dr. G. Huguenin, formerly professor of psychiatry and chief of the medical clinic at Zurich, aged 80.—Dr. C. Grube, instructor in physiology at the University of Bonn, aged 53.—Dr. H. Marx, author of several works on medicolegal questions, aged 45.—Dr. H. Schwiening, chief of the medical statistics service at Berlin, aged 50.—Dr. M. Stolz, professor of gynecology at Graz.—Dr. Gurrucharri, dean of the watering place physicians of Spain.—Dr. H. Triboulet, physician in chief of the Trousseau Hospital at Paris, aged 56.

The Five Hundredth Anniversary of the Rostock University.—The University of Rostock celebrated recently with much formality the quincennial of its foundation. The other German universities were represented officially by Professor Pels-Leusden, from the daughter university at Greifswald, the Danish university was represented by Professor Johannsen of Copenhagen, and the Swedish academics of science by the explorer, Sven Hedin. Professor Lundström of Göteborg presented in the name of the Swedish Reichsverein an endowment of 300,000 marks for fellowships for

northland students at the Rostock University. Honorary degrees were conferred on the German surgeons Madelung and Trendelenburg; and the Berlin physicists Einstein and Planck were elected honorary members of the medical faculty. Prof. R. Kobert of the University of Rostock, whose name is well known for his research on pharmacology and physiologic chemistry, did not live to see the celebration, his death occurring earlier in the year. Rostock is nearly south of Copenhagen, on the Baltic coast.

LATIN AMERICA

Quarantine Against Havana.—The Superior Board of Health of Mexico has decided to place in quarantine all ships from Havana because of the epidemic of meningitis in that city.

Smallpox Epidemic in Mexico.—It is officially announced that there have been outbreaks of smallpox in the states of Sonora, Chiapas, Oaxaca, Morelos, Chihuahua and Guerrero. The disease continues to spread.

Gorgas in Charge of Sanitation in Peru.—Major-Gen. W. C. Gorgas has been placed in charge by the government of Peru of all sanitary works, to be conducted on the seacoast of that country for the purpose of eradicating and preventing yellow fever, plague and other diseases. Dr. Gorgas' official title will be director general of sanitation, and his salary 30,000 soles (about \$15,000).

Deaths in the Profession.—Dr. Liborio Zerda, professor of medicine and the natural sciences at Bogota for three generations of students, regent for many years of the medical faculty, and later ministro del despacho ejecutivo in the department of public instruction, member of various scientific societies at home and abroad and author of several works, including "Higiéncia" and "Visión y Luz," aged 85.—Dr. Luis Alonso y Patiño of Durango, Mexico, former governor of the state of Durango.

Government Services

Public Health Service Takes Over Army Hospitals

The War Department has turned over to the Public Health Service the Whipple Barracks in Arizona and the Fort William Henry Harrison Post in Montana. These posts are of such a character that, in the opinion of the Public Health Service officials, they can be readily converted for the use of Army service patients at a minimum of expense. Thus, the construction of new buildings at high cost for hospital purposes will be avoided.

Disease Conditions in the Army for the Week Ending March 24

There has been a slight recrudescence of influenza at Camps Gordon, Dodge and Jackson, with a slight addition in pneumonia admissions as well. Measles continue about the same, eighteen new cases being reported from Camp Knox. The admission and noneffective rates continue to show slight decline. A comparison of admission rates for influenza and pneumonia and the admission rates for disease during the epidemic period of 1918 as compared with 1920 indicates that the recent epidemic was much less severe. The highest death rate for disease during each epidemic occurred during the fourth week.

Appropriation Requested for Public Health Service

The Surgeon-General of the Public Health Service has made request of the Committee on Appropriations of the House for an appropriation of \$500,000. This is intended to be used, in addition to \$700,000, heretofore granted by Congress for hospital and sanatorium facilities in army service cases. The funds now requested are to be particularly employed in completing alterations on properties already secured from other government departments. Included in these is the Philadelphia Naval Hospital, which will be used by the Public Health Service as a hospital for neuropsychiatric patients. This work will cost, it is estimated, \$75,000. The hospital will have a capacity of 375 beds. By the expenditures of this \$75,000 on the Philadelphia Hospital, the Public Health Service will secure a property the duplication of which, it is claimed, would cost more than a million dollars.

MADRID

Feb. 10, 1920.

Scientific Courses Organized by the Board of Graduate Studies

The Board of Graduate Studies is a state agency headed by Cajal. The secretary, Don José Castillejo, is always on the lookout for professors who may contribute to the spread of experimental science in Spain. Its courses are practical. The board, in previous years, has brought to Spain A. Fournau of the Pasteur Institute, who gave a course on drug synthesis; Urbain of the Sorbonne, who lectured on physical chemistry; Hadamard, also of the Sorbonne, who lectured on mathematics, and Leclerc du Sablon of Tolosa University, who gave a course on vegetal physiology. The board has broadened its efforts, and is now announcing courses by Prof. Lewis Knudson of Cornell University on vegetal physiology; Miss Louise Cheever of Smith College on nineteenth century English literature; Professor Mazé of the Pasteur Institute, on the dairy industry; Professor Pettit of the Pasteur Institute, on bacteriology, and Professor Frouin, on the physiology of digestion. Meanwhile, courses have already been begun by Professor Gutierrez of the Buenos Aires University on the anatomic foundation of surgery, and Professor Fuchs of Vienna on ocular pathology. Professor Avelino Gutierrez is a Spaniard, who has made a name for himself in Argentina. His first lecture was attended by all the professors, many physicians, and all the students. His first lecture illustrated the method followed throughout his course. He showed on the cadaver the parotid region, emphasizing the value of anatomy in order to operate without danger and locate without trouble the most delicate organs.

FUCHS' COURSE

Professor Fuchs' course has greatly impressed the Spanish ophthalmologists, even if all of them are familiar with the great work accomplished by the professor of ophthalmology of the University of Vienna. With the aid of a projection apparatus, Fuchs lectures in Cajal's laboratory, and discusses his collection of 700 different preparations, which he brought from Vienna and which represent his life's work. Some have been obtained under such circumstances that it would be practically impossible to duplicate them, and many were the starting point for new doctrines, which have now become ophthalmologic tenets. Fuchs, who had made a fortune of several million kroner, is one of the victims of the war, and after retiring from his chair was compelled to accept the proposition of the Board of Graduate Studies. This gave him the opportunity to spend a few months away from the city of hunger, the once gay Vienna, which used to be so popular among young American physicians. The case of Fuchs, who has always kept apart from all hatred, being a soldier only in the army which fights pain and disease, is tragic. An old man, after retiring from his profession, and no longer able to replace what he has lost, he has been compelled to abandon his country, bid good-bye to his family, and accept the offer of a few lectures; and still, this scientist, this worshipper of science, puts into his course an enthusiasm, and we may say love, which is full of life, and he demonstrates his anatomic specimens with so much pleasure and fervor that he seems to forget himself and rises to the serene heights of science.

Attack on the School of Medicine

The Senate is still discussing the law for the self-government of universities, and we already begin to see signs in

the newspapers and the academies that the universities do not deserve this privilege. Dr. Lafora, a prominent neurologist, educated in the United States, delivered a lecture in the Atheneum of Madrid attacking the School of Medicine of Madrid, as regards its buildings, its organization and its professors. His criticism was very bitter, and it attracted much attention, because of Dr. Lafora's prominence. It received, however, even more publicity through the defense made by the dean and professor of gynecology of the same school, Dr. Don Sebastián Recasens, who, if anything, made things worse. He agreed that there was need for new buildings, and did not answer Dr. Lafora's charges regarding the organization and professors of the school. In general, it seemed as if Dr. Recasens was trying to defend himself, and forgot all about the others.

LONDON

March 6, 1920.

Proposed Chair of Radiology

It is proposed to establish a chair of radiology at a university as a memorial to Mackenzie Davidson. This pioneer began as an ophthalmologist, and it was only in order to obtain help in his eye work that he turned to the roentgen rays. Soon he was enthralled by their possibilities, and he set himself to master the new craft. Of his important researches the best known is his "cross thread" method of localizing foreign bodies, which was used extensively in the war. An appeal for funds to establish the chair is published over the signatures of public men, scientists and leaders of the medical profession. It is pointed out that, remarkable as has been the development of radiology during the war, watchfulness is necessary lest full advantage be not taken of this stimulus and a period of reaction set in. There is pressing need of unremitting research. For this the best equipment possible is required and also a more thorough and systematic scheme of teaching. The University of Cambridge is alive to these requirements and has established a diploma in radiology and electrology. It is felt that the success of this step will be greatly assured if similar facilities are provided in London. The death of Mackenzie Davidson in the prime of life deprived radiology of its foremost exponent. He was unsparing in his efforts to raise the status of radiology among the sciences and was insistent on the fundamental value of physics, particularly in regard to methods of measurement and the designing of equipment. Many in his own branch of the profession, and a number of his friends and former patients, wishing to keep his memory green, have suggested that an appeal for funds should be made to found a Mackenzie Davidson chair of Radiology at some university. Until quite recently, radiology has been regarded as a purely medical subject; but experimental researches have shown that it is of commercial use. A new subject, radiometallography, has come into being and offers great possibilities for examining the internal structure of metals and other material—a further reason for the proposal.

Awards for Scientific Discoveries

The proposal that state awards should be made for scientific discoveries has been recommended by a joint committee of the British Medical Association and the British Science Guild (*THE JOURNAL*, Jan. 31, 1920, p. 337). A deputation from the Medical Committee of the House of Commons has waited on Mr. Balfour and asked that the government initiate a system of awards for medical and scientific discoveries. The deputation suggested the setting aside of \$100,000 a year on the lines of the Nobel prizes. Mr. Balfour received the deputation sympathetically, but pointed out the difficulty of settling priority in scientific discovery. He urged that a better method would be to put investigators in a more com-

fortable position for carrying on research work. As an aftermath of the representations of the deputation, the medical members of Parliament are considering the advisability of forming themselves into a committee to further the scheme of pensions for scientific men who have enriched the world by their discoveries. The view that it would be difficult to determine who are the proper recipients of pensions is not considered valid. Nor does the proposal to expend the money in further endowments of the Medical Research Committee find favor. The committee has done good work, but it cannot be maintained that original genius will not show itself outside the ranks of its staff.

The International Organization of Medical Societies

At the house of the Royal Society of Medicine, an informal meeting has been held to hear Dr. F. F. Simpson, who is on a mission from the United States of America to explain to the allied profession of Europe a scheme for the simultaneous meetings of international associations in the various departments of medicine. The idea is that in each country there should be a national association for each department of medical science, such as anatomy, physiology, surgery and gynecology, and that the national associations should be linked together to form international associations. There would be an international council to keep the various international associations in relation to one another to arrange for simultaneous meetings in selected countries. Dr. Simpson proposed the immediate constitution of a provisional committee, consisting of two representatives each of Belgium, France, Great Britain, Italy and the United States, which might meet in March to draw up suggestions to submit to certain congresses which are to be held in Paris this year. Sir Wilmot Herringham, who was the general secretary of the last international congress, held in London in 1913, criticized the proposal and has given his views in a letter to the *British Medical Journal*. International congresses, he says, have been open to all comers, and have in consequence become immense pleasure parties rather than centers of serious work. The proposed organization rests on permanent international associations, such as now exist in surgery, gynecology, etc., and are composed of those specially interested in the subjects, who are already in the habit of holding international conferences and meet for work rather than play. It was expressly stated that the new organization was not intended to supersede international medical congresses. Sir Wilmot hopes that these will die a natural death. The staff of the new organization will be more permanent than that of the old. In the new scheme Sir Wilmot Herringham finds nothing to criticize except that there is not enough business to keep alive either the proposed national executive council or the international executive council. Men will not take trouble for business that is formal. A serious disadvantage is that only allied countries will be admitted to the organization. It is not yet possible to meet enemy nations in a friendly spirit, and it will be long before that time comes about. Yet at some time or other international animosities will be softened. But an organization confined to the Allies, and yet calling itself international, is a way to perpetuate the feud which it is the interest of the world to compose. The meeting finally decided to ask the council of each of the sections of the Royal Society of Medicine and of any other suitable body whether it desires international organization for its specialty.

Osler's Successor

Sir A. E. Garrod, physician to St. Bartholomew's Hospital, who was recently appointed director of the clinical unit, has been appointed regius professor of medicine in the University of Oxford in succession to Sir William Osler. He is also consulting physician to the Hospital for Sick Children, Great

Ormond Street. He is 62 years of age and is the son of the Dr. Garrod who discovered uric acid in the blood in gout. His work has been mainly on diseases of metabolism, in which he is a distinguished authority. His publications, which are all of the first importance, include: "Treatise on Rheumatism and Rheumatoid Arthritis"; "Inborn Errors of Metabolism"; "Enterogenous Cyanosis"; "Urine" and "Uremia" (in Osler and McCrae's System of Medicine); "Urinary Pigments in Their Pathological Aspects," and "Glycosuria."

PARIS

Feb. 19, 1920.

Present State of Medical Journalism in France

The war and the economic crisis that followed it have brought about a serious state of affairs in medical journalism. Most of the journals that ceased publication during the war have resumed publication, but some have disappeared. The *Semaine médicale*, established in 1881, has ceased publication. During the thirty odd years of its existence it had acquired a unique position and a universal reputation.

The *Presse médicale* for some time past has been devoting more space to foreign medical current literature. It publishes not only numerous abstracts from medical journals, but also articles of a general nature designed to keep its readers informed in regard to events happening in the medical world (Dr. Pagniez). There is a department of surgery, in the hands of Dr. Lenormant, and a therapeutic department, at the head of which is Dr. Cheinisse.

The *Bulletin médical* has commenced the publication of a special monthly edition for foreign countries. It does not give the reports of societies. The entire first special number was devoted to purulent pleurisy.

The *Gazette des hôpitaux*, since the beginning of the year, has been publishing special numbers devoted to the bibliography of various pathologic subjects.

La Médecine, a monthly review, confines its attention in each number to the progress that has been made in some one branch of medical science; for example, the January issue is devoted to ophthalmology and otolaryngology. At the end of each article it gives a short abstract in both English and Spanish. The *Journal de médecine de Bordeaux* has likewise adopted this plan of short abstracts at the end of articles.

The *Journal de médecine de Paris* has put at the top of its first cover the following request in English: "Please read this paper, you will know the work of the French medicine."

On account of the increased cost of publication the medical journals have been obliged to raise the price of subscriptions. It is doubtless owing to the stress of present economic conditions that the *Journal de médecine de Paris* makes an announcement that one does not expect to find in a medical journal: "Persons sending in ten subscriptions at one time will be entitled to one subscription free."

In order to make it easier to cope with the present unfavorable economic conditions, the *Journal des Praticiens*, which recently published an editorial on the significant subject, "Scientific Journals in a Life and Death Struggle," has demanded that government subsidies, instead of going to political journals as at present, should be given to aid in the publication of scientific journals.

The Belgian medical review, *Le Scalpel*, points out another way of securing relief, which may be applicable to the Belgian medical press at least. Generous America having recently given to the Belgian universities a considerable sum of money to be used in subsidizing scientific research, *Le Scalpel* offers the suggestion that the scientific press of Belgium might experience a happy secondary reaction from this example of American generosity, if the scholars to whom the benefits primarily inure would be disinterested enough to furnish the

scientific press with gratuitous reports of their investigations and discoveries.

A new provincial journal, the *Journal de médecine de Lyon*, has appeared. It is a bimonthly and is published under the scientific direction of Profs. Joseph Teissier, Edmond Weill, Jean Lépine (son of the late Raphael Lépine), and others. It is devoted especially to the publication of news and of medical articles contributed by the physicians of the region about Lyons.

Among the special journals I may mention the *Revue de gynécologie et de chirurgie abdominale*, of which the late Prof. Samuel Pozzi was the managing editor, but which has now ceased publication. The *Annales de gynécologie et d'obstétrique*, at the head of which were Professors Pinard, Hartmann and Pollosson, and the *Archives mensuelles d'obstétrique et de gynécologie*, of which Profs. Paul Bar and J.-L. Faure were managing editors, combined the first of the year and now constitute a single review known as *Gynécologie et Obstétrique*.

Lethargic Encephalitis

New cases of lethargic encephalitis are reported from almost every section of the country. However, it would now appear that the situation is by no means as serious as was at first supposed. The Conseil d'hygiène of the department of the Seine has deemed it wise to call the attention of the Corps médical to the appearance of the disease in question and to the desirability of receiving from physicians reports of all cases that they may have an opportunity to observe. The Académie de médecine, at the suggestion of Dr. Netter, has likewise requested that physicians report to the academy all cases of undoubted and doubtful lethargic encephalitis that they may observe.

Serums Furnished by the Paris Pasteur Institute

Since 1894 the Pasteur Institute had been furnishing gratuitously to all prefectures all the diphtheria antitoxin needed in hospitals and in free dispensaries for the poor. Since the discovery of new serums the prefects had demanded not only diphtheria antitoxin, but also all the new serums, and especially the serums used against tetanus, the meningococcus, the streptococcus and the pneumococcus. While pharmacists were in the habit of keeping on hand a supply of diphtheria antitoxin, they did not, as a rule, have the other serums in stock, and, as the physicians could procure them only in the prefectures, the result has been that serums intended for the poor have been used for the treatment of patients who are able to pay.

In view of this condition of affairs, it has been decided that the Pasteur Institute will continue to provide serums directly and gratuitously to the hospitals, but that for serums furnished to physicians, private individuals, and public prophylactic services a charge will be made through the pharmacists from whom they may be secured. The pharmacists will procure their stocks through their associations and the latter will be provided for by the Pasteur Institute. Furthermore, no speculation will be tolerated on the part of the pharmacists, the highest price that can be charged for any serum furnished by the Pasteur Institute being 4 francs per dose.

Marriages

THOMAS ALBERT WILLIAMS, Middletown, Va., to Miss Marie Pittman of Charles Town, W. Va., in Washington, D. C., February 11.

ROBERT WALDORF FISHER to Mrs. Emily White Mills, both of Morgantown, W. Va., February 13.

MILLARD WILSON HALL, Wichita, Kan., to Miss Sadie Hall of Ottawa, Ill., March 10.

Deaths

Frederick Thomas Reyling ☉ Kansas City, Mo.; University of the City of New York, 1884; aged 59; a member of the American Academy of Ophthalmology and Oto-Laryngology; a specialist on diseases of the eye and ear; instructor in histology in his alma mater from 1884 to 1892; professor of materia medica and therapeutics in the New York College of Comparative Histology and Veterinary Surgery, and instructor in diseases of the eye in the New York Post-Graduate School and Hospital from 1889 to 1896; professor of histology and pathology in the University Medical College, Kansas City, from 1899 to 1901, and professor of histology, pathology and bacteriology in the College of Physicians and Surgeons, Kansas City, Kan., from 1901 to 1905; died, February 24, from pneumonia.

Shobal Vail Clevenger, Chicago; Chicago Medical College, 1879; aged 77; a veteran of the Civil War; chief engineer of the Southern Dakota Railway; special pathologist to Cook County Institutions, Dunning; superintendent of the Illinois Eastern Hospital for the Insane, Kankakee, in 1893; for several years neurologist to the Alexian Brothers and Michael Reese hospitals; lecturer on art anatomy at the Chicago Art Institute, on physics at the Chicago College of Pharmacy and on medical jurisprudence in the Chicago College of Law; a prolific contributor to medical literature; one of the founders and first secretary of the Chicago Academy of Medicine; author of a two volume work on "Medical Jurisprudence of Insanity"; died, March 24, from cerebral hemorrhage.

Kimbell W. Leland, Utica, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1879; Rush Medical College, 1892; aged 62; a member of the Illinois State Medical Society; president of the LaSalle County Medical Society in 1899; formerly mayor and health officer of Utica, and president of the Utica school board; chairman of the board of directors of the new LaSalle County Tuberculosis Sanatorium, South Ottawa; died in St. Mary's Hospital, LaSalle, Ill., March 12, from pneumonia.

Charles Edward Whiteside, Moline, Ill.; College of Physicians and Surgeons, Chicago, 1894; aged 50; a member of the Illinois State Medical Society; once alderman of Moline; lieutenant and assistant surgeon, Illinois National Guard, and assigned to the Sixth Infantry during the war with Spain; died in the North Chicago Hospital, Chicago, March 20, from carcinoma of the lower jaw.

Frederick Jacob Leviser ☉ New York City; University of Goettingen, Germany, 1884; aged 59; a specialist in dermatology; a member of the American Dermatological Society and New York Academy of Medicine; consulting dermatologist to the Montefiore Home and Hebrew Orphan Asylum, and chief of the dermatological clinic of Mt. Sinai Hospital; died, March 9.

William Charles Chilson ☉ Tulare, Calif.; University of California, San Francisco, 1902; aged 43; Captain, M. R. C., U. S. Army, with service overseas, and discharged September 4, 1919; was found dead in a hotel in Fresno, Calif., March 10, from the effects of a gunshot wound of the heart, believed to have been self-inflicted, with suicidal intent.

William Teel Montgomery ☉ Chicago and Evanston, Ill.; Rush Medical College, 1871; aged 76; a veteran of the Civil War; a specialist on diseases of the eye and ear; oculist to Presbyterian Hospital, and a trustee of the Illinois State Charitable Eye and Ear Infirmary; died in Evanston, March 25.

John Loren McAllister, Martinsville, Ohio; Ohio Medical University, Columbus, 1905; aged 39; a member of the Ohio State Medical Association; captain, M. R. C., U. S. Army, and on duty with the Eighty-Fourth Division, A. E. F., in France, and discharged Aug. 22, 1919; died, March 12, from influenza.

Allen R. Holshouser, Rockwell, N. C.; Chattanooga (Tenn.) Medical College, 1904; aged 66; while driving in an automobile over a grade crossing near Sallsbury, N. C., February 24, was struck by a locomotive, fracturing both legs and causing other injuries, from which he died, February 26.

Louis B. Carson, Maquoketa, Iowa; Hahnemann Medical College, Chicago, 1892; aged 47; a member of the Iowa State

☉ Indicates "Fellow" of the American Medical Association.

Medical Society; captain, M. R. C., U. S. Army, and discharged March 19, 1918; supreme medical director of the Home Guards of the World; died, March 10, from heart disease.

James Lenox Rea ♂ Scranton, Pa.; Jefferson Medical College, 1876; aged 65; once president of the Lackawanna County Medical Society; consulting physician to the State Hospital for Northwestern Pennsylvania, Scranton; surgeon of the Delaware and Hudson Railroad; physician to the Oral School for the Deaf, Scranton; died, February 22.

George Read Skinner, Marion, Iowa; Bellevue Hospital Medical College, 1866; aged 83; a member and once treasurer of the Iowa State Medical Society; consulting surgeon to St. Luke's Hospital, Marion; a veteran of the Civil War; died at the home of his son in St. Louis, March 10.

Willoughby C. Kline, Myerstown, Pa.; University of Pennsylvania, Philadelphia, 1872; aged 69; for many years a druggist and practitioner of Myerstown; a member of the state pharmaceutical association, and a director of the Myerstown Trust Company; died, March 15.

Vincent Joseph Campisi, Brooklyn; Long Island College Hospital, Brooklyn, 1914; aged 32; was summoned to a tenement house in Brooklyn, March 25; and was found there stabbed to death. The body of the supposed patient was found in the same room strangled to death.

Julian Bezel Beck, Chicago; College of Physicians and Surgeons, Chicago, 1904; aged 43; a member of the Illinois State Medical Society; assistant professor of dermatology in Loyola University; died in Mount Sinai Hospital, Chicago, March 25, from cerebral hemorrhage.

James P. Saffold, Washington, D. C.; Columbian University, Washington, D. C., 1885; aged 65; since 1888 an employee of the Treasury Department and assistant chief of division in the office of the Auditor for the Navy; died, February 29, from heart disease.

Pierre S. Starr, Hartford, Conn.; University of the City of New York, 1862; aged 89; assistant surgeon of the Thirty-Ninth Ohio Volunteer Infantry during the Civil War; who fell and fractured his hip, February 27; died in the Hartford Hospital, March 11.

William A. Batchelor ♂ Milwaukee; University of Pennsylvania, Philadelphia, 1884; aged 63; surgeon to the Milwaukee Hospital, Illinois Steel Company, and Chicago, Lake Shore and Eastern Railroad; died in Cleveland, March 18, from heart disease.

William Ralph Buchanan, Major, M. C., U. S. Army, Washington, D. C.; Hahnemann Medical College, Philadelphia, 1902; aged 49; who was undergoing physical reconstruction; died in the Walter Reed General Hospital, Takoma Park, D. C., March 5.

Samuel Hollis, Hartford City, Ind.; Kentucky School of Medicine, Louisville, 1879; aged 68; a member of the Indiana State Medical Association; while making a professional call near Hartford City, March 13, died suddenly from heart disease.

Walter McTaggart, Harrisburg, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1884; aged 57; a member of the Illinois State Medical Society; died at the home of his daughter in Mt. Vernon, Ill., March 11, from septicemia.

Daniel Russell Phillips, Leavenworth, Kan.; College of Physicians and Surgeons in the City of New York, 1887; aged 56; a member of the Kansas Medical Society; died in Topeka, Kan., March 5, from myocarditis.

Walter Thomas Hall, Toulon, Ill.; Medical Department University of Iowa, Keokuk, 1869; aged 79; once president of the Stark County Medical Society and president of the board of health of Toulon; died, March 8.

William W. Ray, Eastover, S. C.; Kentucky School of Medicine, Louisville, 1886; aged 61; a member of the South Carolina Legislature in 1884; died in the Columbia (S. C.) Hospital, March 1, from angina pectoris.

Barton Pitts, St. Joseph, Mo.; University of Maryland, Baltimore, 1881; aged 60; a member of the Missouri State Medical Association; a specialist on diseases of the eye and ear; died, March 10, from heart disease.

Robert Charles Dickinson, Brundidge, Ala.; Memphis (Tenn.) Hospital Medical College, 1901; aged 50; a member of the Medical Association of the State of Alabama; died, about March 4, from heart disease.

Jonathan Franklin Richardson, Wankegan, Ill.; Medical Department, University of Iowa, Keokuk, 1864; aged 83; for many years a practitioner of Keota, Iowa; died, March 18.

Lee Roy Burdeshaw ♂ Headland, Ala.; Chattanooga (Tenn.) Medical College, 1899; aged 44; once president of the Henry County Medical Society; died, March 6, from cardiorenal disease.

James B. Campbell, London, Ont.; Western University, London, Ont., 1898; associate professor of physiology and later associate professor of medicine in his alma mater; died, February 9.

Martin Toner Balsley ♂ Joplin, Mo.; Medical College of Indiana, Indianapolis, 1881; aged 66; formerly of Indianapolis and Danville, Ill.; died, about March 13, from valvular heart disease.

Logan D. Berry, Danville, Ga.; Atlanta School of Medicine, Atlanta, Ga., 1909; aged 38; a member of the Medical Association of Georgia; died, about February 29, from influenza.

Ernest Major Jordan ♂ Boston; Boston University, 1899; aged 48; for seven years professor of nervous diseases in his alma mater; died, March 13, from pernicious anemia.

Bruce Raynor Leighton ♂ Kalamazoo, Mich.; Western Reserve University, Cleveland, 1912; aged 36; died in the Boggess Hospital, Kalamazoo, January 24, from pneumonia.

George S. Carter, Beckville, Texas (license, Sixth Judicial Board, Texas, 1889); aged 58; died at the home of his daughter in Marshall, Texas, March 4, from tuberculosis.

Richard McSherry, Littlestown, Pa.; University of Maryland, Baltimore, 1880; aged 64; for many years a practitioner of Baltimore; died, March 12, from cerebral hemorrhage.

Archie B. Atchison, Winnebago, Ill.; Hahnemann Medical College, Chicago, 1899; aged 49; died in Irvington, Ala., March 9, from heart disease following influenza.

Samuel Vincent Romig, Chicago; University of Michigan, Ann Arbor, 1872; aged 78; for many years a practitioner of Rockford and Winnebago, Ill., died, March 8.

Nicholas C. Trout ♂ Fairfield, Pa.; Jefferson Medical College, 1896; aged 53; a director of the Gettysburg National Bank; died, March 23, from diabetes.

J. Carl Smith, Ellerslie, Md.; Baltimore University, 1888; aged 59; died in Franklin Square Hospital, Baltimore, February 28, from cerebral hemorrhage.

Layton W. Cooke, Fruitdale, S. D.; College of Physicians and Surgeons, Keokuk, Iowa, 1884; aged 68; died, about March 12, from pneumonia.

Charles E. Schmitz, Cambridge, Ida.; Barnes Medical College, St. Louis, 1903; aged 40; died, February 23, from pneumonia following influenza.

Richard H. Disse, St. Louis; St. Louis College of Physicians and Surgeons, 1887; aged 51; died, March 8, from cardiorenal disease.

Julius Goldsmith, New York City; Eclectic Medical College of the City of New York, 1905; aged 46; died, March 10, from pneumonia.

Edwin R. Baker, Philipshurg, Ohio; Medical College of Ohio, Cincinnati, 1876; aged 68; died, March 5, from bronchopneumonia.

Charles Lee Holloway, St. Joseph, Mo.; Kansas City (Mo.) Medical College, 1885; aged 53; died, February 22, from diabetes.

Boston N. Speer, Monclova, Coahuila, Mex.; Chattanooga (Tenn.) Medical College, 1897; died, March 14, from heart disease.

Ethan Allen DeCamp ♂ Flint, Mich.; Detroit College of Medicine, 1900; aged 55; died, March 7, from malignant disease.

George Sumner Provine ♂ Blandinsville, Ill.; University of Illinois, Chicago, 1906; aged 37; died recently from appendicitis.

Rufus H. Starks, Benton, Ky.; Louisville, Ky., Medical College, 1888; aged 67; died, February 26, from dysentery.

Helen E. Hill, Brooklyn, N. Y.; Eclectic Medical College of the City of New York, 1881; aged 80; died, March 20.

Alexander O'Neil, Lansing, Mich.; University of Michigan, Ann Arbor, 1868; aged 72; died, March 4.

William Stairs Morrow, Montreal; McGill University, Montreal, 1881; aged 50; died, recently.

Correction.—A telegram from Dr. William C. Hassler, health officer of San Francisco, whose death was erroneously noted in THE JOURNAL of March 27, states that he has been ill with influenza, but has recovered.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

ANTI-TUBERCULOUS LYMPH COMPOUND (SWEENEY) AND ANTI-SYPHILITIC COMPOUND (SWEENEY)

Reports of the Council on Pharmacy and Chemistry

The Council has authorized publication of the reports which appear below, declaring Anti-Tuberculous Lymph Compound (Sweeney) and Anti-Syphilitic Compound (Sweeney) ineligible for New and Nonofficial Remedies.

W. A. PUCKNER, Secretary.

Anti-Tuberculous Lymph Compound (Sweeney)

"Anti-Tuberculous Lymph Compound (Sweeney)" is put out by the National Laboratories of Pittsburgh, Dr. Gilliford B. Sweeney, "Medical Director." Sweeney has claimed at different times that he became interested in the subject of von Behring's efforts to immunize cattle to tuberculosis at a time when he was an assistant in von Behring's laboratory. He claims to have conceived the idea while there of transferring bovine immunity to tuberculosis to the human subject and later to have evolved his "treatment" at the Pasteur Institute in Paris.

Just how Anti-Tuberculous Lymph Compound is made today is not stated—at least so far as one is able to learn from recent advertising. Some years ago Sweeney declared that his "Anti-Tubercular Lymph" (as it was then called) was derived from a bullock which had been immunized to tuberculosis. Then:

"The immunized animal having been slaughtered, the contents of the lymph reservoirs are carefully collected and an aqueous extract is made from the grey cerebral substance, spinal cord and the lymph glands. It is then filtered under high pressure and de-albuminized by succussion. To this, the lymph, together with a definite proportion (50 per cent.), of the naturally phosphorized brain rats is added, with a small amount of chloride of gold (about 1-60 gr. to the dose), the latter as a preservative."

It is a fair assumption that however the preparation may have been made originally, it is not now made in such a manner as to bring it under the federal laws governing the preparation of serums and similar preparations. The claims made for Anti-Tuberculous Lymph Compound are of the usual uncritical and unscientific type. Mainly, of course, they are of the testimonial class. The physician is told that the preparation has been carefully tested by men whose judgment is worthy of consideration; that the verdict has been altogether favorable to the "Compound." Thus:

"... the remedy was submitted to a selected body of skilled physicians, recognized for their skill and care in making therapeutic observations. These men represented widely varying conditions, climatic and otherwise. Those who said ten years ago that Anti-Tuberculous Lymph Compound has a specific immunizing influence upon the tuberculosis patient, find the same to be true today."

Careful reading of the matter just quoted will reveal its ambiguity and inherent lack of frankness. The inference conveyed is that the "selected body of skilled physicians" have unqualifiedly endorsed Anti-Tuberculous Lymph Compound (Sweeney)—but it does not say so!

It is the history of all such preparations, introduced to the medical profession with the usual blare of trumpets, that a certain number of favorable testimonials can be obtained. It is also the history of such products that one has but to wait a few years and the physicians who had written most enthusiastically regarding the preparation—in the first flush of their optimism following its use and the perusal of the manufacturers' literature—will acknowledge that they were mistaken in their original estimate and are no longer using the agent. In this connection an investigation of some of the

old testimonials for Anti-Tuberculous Lymph Compound by the Propaganda department of THE JOURNAL is instructive.

In a somewhat elaborate booklet published in 1907 by Sweeney, an Indiana physician was said to have reported favorable results following the administration of the "lymph." A letter written to this physician in October, 1919, asking for his present opinion on the product brought this reply, in part:

"... it being twelve years since using the serum and no reference or repeated orders since should surely suffice as evidence of my lack of faith in the serum. . . ."

An Illinois physician was reported in the same booklet to have described a case of a young man with an active tuberculosis, who was given injections of the "lymph" in February, 1907. The patient, it was claimed, showed immediate improvement and the Sweeney booklet (published in August, 1907) stated that "improvement in this case continued and terminated in complete recovery." A letter written to the physician in October, 1919, brought out the fact that the young man in question, after receiving "Anti-Tuberculous Lymph Compound" and other treatment was removed "on a stretcher" "to New Mexico, where he remained for three or four years" and recovered. The doctor adds:

"I do not think that the Anti-Tuberculous Lymph had anything to do with the man's recovery, although I realize the difficulty of definitely analyzing just what did effect the cure. I did since that time use that preparation in several other cases without beneficial results so that I gave it up a good many years ago adding it to that large heap of pharmaceutical material 'weighed and found wanting.'"

A physician in Texas also reported in the 1907 booklet as having had very satisfactory results with the Anti-Tuberculous Lymph Compound in one case of pulmonary tuberculosis was written to in October, 1919. He replied:

"I will state that subsequent use of this compound did not bear out the apparent good results from its use in the first case or two."

In a "Bulletin" issued by the Sweeney concern in 1912, a Pennsylvania physician was quoted as having treated three cases with Anti-Tuberculous Lymph Compound with resultant cures. This physician was written to in October, 1919, and he replied:

"I have no knowledge of the use of my name by any Pittsburgh concern and know nothing of a lymph of the name of Sweeney; neither do I recollect ever curing three cases of tuberculosis with any lymph."

The same "Bulletin" quoted the alleged statement by a Delaware physician to the effect that he believed Anti-Tuberculous Lymph Compound to be the most successful treatment of tuberculosis extant. This in 1912. To an inquiry sent in October, 1919, this physician briefly replied:

"Am not using it now."

The result of the Propaganda department's questionnaire was what might have been expected. Every physician who answered the inquiry regarding his previous and present opinions of Anti-Tuberculous Lymph Compound (Sweeney) declared, in effect, that he had long since ceased to have faith in its value or efficacy.

According to claims made in the Sweeney literature, "Anti-Tuberculous Lymph Compound exercises its immunizing power through a specific action upon the blood cells." The statement that "it destroys the tuberculosis germ when this is present in the system of the patient" is untrue. The facts are, no serum or lymph has thus far been proved to have any value in the treatment of tuberculosis even when fortified by "a small proportion of chloride of gold and soda" as one circular tells us the "lymph" is. In spite of years of research by competent investigators, we are still without any aid in the form of a serum in the treatment of tuberculosis.

Anti-Tuberculous Lymph Compound (Sweeney) is one of those preparations that need no elaborate laboratory tests, nor even exact therapeutic research, to convince any clear-thinking person that it is patently and obviously worthless. One would hesitate before asking any reputable clinician to test a preparation of this sort. It is a constant source of surprise that some physicians allow themselves to be persuaded by advertising literature that is obviously uncritical and unscientific, to use preparations which have no more reasonable foundation than this one.

The Council declares Anti-Tuberculous Lymph Compound (Sweeny) not acceptable for New and Nonofficial Remedies.

Anti-Syphilitic Compound (Sweeny)

This preparation also is made by or under the direction of the same Dr. Gillford B. Sweeny whose researches (?) led to the production and evolution of the Anti-Tuberculous Lymph Compound (Sweeny). According to the data at hand, this preparation is made by suspending benzoate of mercury in lymph from the bullock. Case reports are given of alleged cures of syphilis after two months of treatment; indeed, the circular exploiting the agent makes the statement that it is seldom necessary to continue the treatment beyond two months, which, if one chose to be credulous, would indicate extraordinary power for the mercury.

Mercury of course has a proper place in the treatment of syphilis, but that any physician could be induced to place his trust in this preparation is almost unthinkable though testimonials—which the "National Laboratories" claim to have received from physicians—are published. They all stamp the writers as not only gullible but also incompetent. The tenor of the claims is on a par with those made for the Anti-Tuberculous Lymph Compound; they do not justify the time required for detailed consideration.

The Council declares Anti-Syphilitic Lymph Compound (Sweeny) not acceptable for N. N. R.

Correspondence

FACTS LEADING TO PUBLICATION OF "ARMY FROWNS AND SMILES"

To the Editor:—There has come to my attention the following advertisement of a book published by Dr. D. E. Compere, formerly a first lieutenant in the Medical Corps:

"A 'RED HOT' BOOK JUST OFF THE PRESS

ARMY FROWNS and SMILES

By Dr. D. E. Compere
(First Lieut. M. C. U. S. Army)

Pulling the Cover OFF OFFICIAL ROTTENNESS

Flavored by the Soldier's Courage
Shield, A SMILE

DEDICATED

To the memory of an ORPHAN, Private
Russell A. Wood, No. 673d Aero Supply Squad-
ron, A. C. S. D. & C. C., who died October 11,
1918, at Camp Morrison, Va., WITHOUT
PROPER MEDICAL ATTENTION."

"Also to the memory of each noble HERO who made the supreme sacrifice and gave his life for our country, but especially to all those who died the result of hard boiled, cold blooded, callous neglect.

"I served in the Medical Corps nearly twelve months and learned of ROTTENNESS which is a disgrace to any civilized nation, and America will not approve and WHITE-WASH. Therefore, it is now my DUTY to tell the PUBLIC these FACTS, and if they desire conditions to continue as bad or even worse, such is their privilege, BUT I HAVE DONE MY BIT."

"I had rather be branded as a belly-acher than as a shut-mouth. To know that such rottenness exists and keep quiet is a thousand times worse than to be misunderstood."

"THIS WORLD WAS WON BY FREE MEN FOR THE FREEDOM OF MANKIND; YET, JUSTICE CANNOT BE SECURED THROUGH THE CHIEF OFFICIALS OF THE UNITED STATES OF AMERICA."

"Convenient RULES, protecting a wonderful system of 'SUPPOSED TO BE' Justice in FREE America, when the TAXPAYERS, THE VOTERS, 'THE BOSS' is not supposed to know or be given copies of, what is being done by some of OUR GOVERNMENT OFFICIALS in the City of Washington, and even though MILITARY LAW is VIOLATED by DEPARTMENT CHIEFS, 'THE BOSS' dare not criticise. 'GREAT STUFF'."

PRICE \$2.00

In view of the fact that many persons who have lost relatives and friends in the service will be deeply troubled by the statements made by Dr. Compere, and, further, because

of the serious reflections on the War Department and on the fidelity and integrity of physicians formerly in the service, it is believed that the true facts in regard to the matters referred to by Dr. Compere should be given wide publicity, and I therefore request that this letter be published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

The matters to which Dr. Compere refers in his book had their origin in the following letter addressed by him to the Surgeon General:

"Camp Hospital, Camp Alfred Vail,
"Signal Branch, N. J., October 23, 1918.

"From: 1st Lt. Dolphus E. Compere, M. C.
To: The Surgeon General, U. S. Army (thru Official Channels).
Subject: Major Butler, Camp Surgeon, Camp Morrison, Va.

"1. At 8:00 P. M. October 8th I received the following telegram from my wife, 'Gano (my brother) seriously ill, pneumonia, mother says, if possible go to him.' At 8:30 P. M. Oct. 8th I wired the Camp Surgeon, Camp Morrison, Va. 'Please wire exact condition of my brother, Cpl. Gano Compere,' signed it Lt. D. E. Compere, Camp Surgeon, Camp Alfred Vail, N. J. After waiting fifteen hours with no reply and upon the suggestion of Colonel Helms, Commanding Officer, Camp Alfred Vail, N. J., at twelve o'clock Oct. 9th I wired the same message again except added 'report delivery.' After no reply at 8:00 P. M. Oct. 9th I wired mother 'Where and how is Gano. Have wired twice, no reply.' At 9:50 P. M. Oct. 9th my mother answers, 'catch first train, Camp Morrison, Va. Gano seriously ill. Heard nothing.' At 7:00 A. M. Oct. 10th the Western Union reports 'Your message to Camp Surgeon, delivered 2:00 P. M. Oct. 9th and at the same time delivered this message 'Condition better today,' signed Major Butler, Camp Surgeon, Camp Morrison, Va. dated 9:42 P. M. Oct. 9th. I find Major Butler did receive both of my messages. He completely ignored the first and waited from 2 o'clock until 9:42 P. M. to answer the second, so after waiting over 36 hours and requesting his exact condition, then to receive such a vague indefinite reply, upon the consent of Colonel Helms I hurried to Camp Morrison. Upon arriving I first met Capt. Steffen who accompanied me to Ward 13 where I found my brother. Capt. Steffen looked at his clinical record then placed it back with the others without showing it to me, then I asked if I might see it. He said 'Yes, of course,' also that my brother was transferred to the Camp Hospital from one of the auxiliary Company Hospitals.' The clinical record shows that he was admitted Oct. 6th at 5 P. M. and his first temperature 100.8 was recorded at 7 A. M. Oct. 7th and has not been 100 since that date. My brother said he came direct from his barracks to this Hospital October 6th at 1 P. M. and Lt. J. D. Nelson took his temperature soon after his arrival. He asked how much fever he had and Lt. Nelson replied 104. I could not prevent hearing and seeing dangerously ill soldiers around my brother, but one especially attracting my attention was unconscious and breathing so fast and hard that as I sat on my brothers cot, I held my watch and found his respiration to be 50 per minute. About 12 o'clock the ward orderly came around giving 1/30 gr. strychnine tablets and Dovers powders and finding he could not prize this poor fellows mouth open with a spoon he remarked 'Oh well, when you can't get their mouths open, there's nothing else to do.' I saw the nurse sitting in the ward record room writing and filling in papers, also I talked with Lt. Nelson, the ward surgeon and hereby testify that absolutely nothing was done for this dying soldier from 8:30 A. M. until after 3 P. M. also my brother said 'All others are treated the same and this soldier Pvt. Woods had been expected to die for three days.' I went to the office and talked with Major Butler about my telegrams and found him to be very insulting and disrespectful. He said, 'Well whats your grouch.' I said promptly 'simply if you had wired me the exact condition of my brother I would not have left my work.' He said 'Oh is that all.' Then I said, 'No and I would like to know if all your cases are allowed to die without attention as I know one man to be doing.' He asked me who sent me down to spy into his business. I replied I was there upon official permission of Colonel Helms my Commanding Officer to visit a sick brother. He said 'if you have any kicks to make about me send them to Washington through official channels.' I assured him this would be done.

(Sgd.) "Dolphus E. Compere,
1st Lt. M. C. Surgeon."

This letter was referred to the commanding officer at Camp Morrison, who, under date of Oct. 18, 1918, stated that in view of the sudden appearance of the influenza epidemic and the widespread fatalities resulting from it, he believed that the Surgeon, Major Benjamin J. Butler, Medical Corps, was entitled to commendation rather than condemnation for the creditable manner in which he handled the emergency. Approximately 50 per cent. of the camp personnel became inmates of the hospital within the period of a few days, and investigation demonstrated that the percentage of fatalities (approximately 3 per cent. of the total number of cases) was lower than in the majority of other camps in the country. He further stated that the accommodations at this camp were inadequate to accommodate such a number of sick demanding treatment within a few days, and that it was necessary to improvise hospital space. To his personal

knowledge, the physicians, nurses and medical attendants left their posts while the epidemic was at its height only long enough to secure essential rest and it was necessary to detail nearly 200 men from the Air Service to assist the regular hospital personnel.

In view of the seriousness of the charges made by Lieutenant Compere, the matter was investigated by the representative of the Inspector General's Department of the Army located at the Port of Embarkation, Newport News, Va. The inspector was Col. J. T. Nance, a retired officer of long experience and high attainments. The investigation covered the period from Oct. 28, 1918, to Nov. 12, 1918, and was thorough. Colonel Nance's conclusions and recommendations are as follows:

"(a) That Lieutenant Compere's allegation that his first telegram was ignored is not sustained by the evidence.

"(b) That his allegation that reply to the telegram was delayed is sustained by the evidence, but that a large part of this delay was incident to poor telegraphic service available and that the remainder of the delay was incident to conditions existing during the epidemic of influenza and pneumonia.

"(c) That his allegation that the reply was vague and indefinite when he had requested information as to the exact condition of his brother is sustained by the evidence.

"(d) That his complaint that Private Wood was being allowed to die without attention; that absolutely nothing was done for this dying soldier from 8:30 A. M. until after 3:00 P. M. is not sustained by the evidence.

"(e) That the complaint that Major Butler was very insulting and disrespectful toward First Lieutenant D. E. Compere is sustained, in a measure, by the evidence. It is remarked in this connection that there were extenuating circumstances; that Major Butler had many cares and responsibilities, and that Lieutenant Compere's presumption and manner were irritating.

RECOMMENDATIONS:

"(a) That Major Benjamin J. Butler, M. C., be instructed to comply in future with Army Regulations No. 824.¹

"(b) That no other action be taken in his case as far as Major Butler is concerned.

"(c) That disciplinary action be taken in the case of First Lieutenant Dolphus E. Compere, M. C., for making the false statement contained in his complaint that 'absolutely nothing was done for this dying soldier from 8:30 A. M. until after 3:00 P. M.'"

The recommendations of Colonel Nance were concurred in by the Commanding General of the Port of Embarkation, Brig.-Gen. H. B. Ferguson, by the Surgeon General, and by the Inspector General, but in view of the fact that Lieutenant Compere had been honorably discharged from the service on Dec. 14, 1918, prior to the receipt of Colonel Nance's report in the office of the Inspector General, it was not practicable to take any disciplinary action in this case, and the Inspector General recommended that notation of the facts disclosed by the investigation be made on the efficiency record of Lieutenant Compere and that no further action be taken. This notation on the efficiency record was made.

About December 15, after his discharge from the service, Dr. Compere appeared in my office and behaved in a very objectionable and discourteous manner. Since that date several communications from him have been received by various officials of the War Department, in which he has made many allegations, more or less exaggerated and incorrect, particularly his frequent assertion that the investigation at Camp Morrison was in the nature of a "white-wash" and was made by an inspector of the Medical Department of the Army, whereas this inspection was made by an officer of the Inspector General's Department, which is the final authority in the military service designated by law to investigate facts in regard to complaints and misconduct.

The foregoing statements are made from no desire to enter into further controversy in regard to the matters in question, but merely to place before the Fellows and members of the

American Medical Association a clear and unbiased statement of the facts leading up to the publication of "Frowns and Smiles." M. W. IRELAND, M.D., Washington, D. C.
Surgeon General, U. S. Army.

CONDITIONS IN VIENNA

To the Editor:—You may be interested in the enclosed excerpt from a letter written me by Lieutenant-Colonel Leach, who has been long connected with Belgian relief, the American army, and the American relief administration.

ROY LYMAN WILBUR, Stanford University, Calif.

President, Leland Stanford Junior University.

I have just been making a survey of conditions among the medical profession here in Vienna with Dr. von Pirquet. There are about 4,500 medical men, and at least 90 per cent. of them are working on half rations, and many are actually on the point of starvation. I had a talk with Prof. Eiselsberg yesterday, who is the leading surgeon of Vienna. In the last year he has lost 20 pounds in weight through insufficient nourishment. He has plenty of Austrian money, but cannot buy from the farmers as they will accept nothing but foreign money of recognized value or will barter for wearing apparel. I was told today in a Vienna shoe store of a peasant who came in and was advised not to spend his money for expensive shoes when he could wear sandals. These same shoes cost 5 kronen before the war. He replied that it really didn't make much difference, as his father and grandfather had always figured a pair of ducks equivalent to a pair of shoes. That simply raised the market value of the ducks. To get eggs, butter or milk in the country, which is the only place they are obtainable at the present, it is necessary to go armed with shoes, silk stockings, underwear, etc. When the surplus of clothes is exhausted there is nothing in sight but starvation.

I have suggested to Professor Eiselsberg that, as president of the Vienna Medical Association, he could make a general appeal to the medical profession in the United States on behalf of our colleagues here, this appeal to be made to our New York office and through their propaganda department, a proper appeal sent to each state medical association with Professor Eiselsberg's description of conditions as they existed here among the profession. Contributions could be made in the form of the Hoover food drafts, deliveries to be made to a committee headed by Professor Eiselsberg in Vienna, who could supervise the distribution of the packages to the most urgent cases.

At present the class which seems to be suffering most from under-nourishment is the aged, the death rate among this class having risen tremendously. The children, of course, are being cared for to a certain extent through our European children's fund operations; but there is no like organization in operation for the benefit of the aged.

"BLOOD TRANSFUSION APPARATUS"

To the Editor:—In regard to the blood transfusion apparatus as described by Dr. L. L. Stanley in THE JOURNAL, March 6, 1920, p. 671, this modification may be made: namely, the stopcock may be substituted for the ball valve arrangement as described.

A glass stopcock with a good sized bore may be substituted for each one of the ball valves, thus shutting off each of the two needles, at will, from the syringe. When the donor's blood is to be drawn, the stopcock leading to his needle is opened, while the one leading to the recipient's needle is closed. The syringe is filled by drawing out the plunger. The donor's stopcock is now closed and the recipient's stopcock opened, and the blood is immediately forced into the recipient's vein by pushing in the piston of the syringe. The advantages of this modification are:

1. It is a relatively simple instrument to make at home.
2. The instrument need not be held in any particular position, since gravity plays no part here.
3. It diminishes the clotting of the blood by eliminating the ball arrangement, which acts as a freely movable foreign body in the incoming and outgoing stream of blood.
4. In the ball valve plan if, because of clotting, the recipient's valve should fail to close properly, the blood filling the syringe will come from his vein as well as from his donor's, a situation which can readily be prevented by the use of the stopcock, and so assure the operator that the blood his patient is receiving is not partly his own.

BARNETT GREENHOUSE, New Haven, Conn.

1. Paragraph 824, Army Regulations, has to do with the rules which govern the furnishing of information, based on military records, which might be used in establishing a claim against the government. This paragraph further provides that information concerning sick and wounded officers and enlisted men will be freely conveyed to allay the anxiety of friends.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

ARIZONA: Phoenix, April 6-7. Sec., Dr. Ancil Martin, 207 Goodrich Bldg., Phoenix.

ARKANSAS: Little Rock, May 11-12. Sec. Regular Bd., Dr. I. J. Stout, Brinkley. Sec. Eclectic Bd., Dr. C. E. Laws, Fort Smith.

COLORADO: Denver, April 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

DISTRICT OF COLUMBIA: Washington, April 13-15. Sec., Dr. Edgar P. Copeland, the Rockingham, Washington.

HAWAII: Honolulu, May 10-14. Sec., Dr. R. W. Benz, 1141 Alakea St., Honolulu.

IDAHO: Boise, April 6. Commissioner, Hon. Robert A. Jones, Boise.

LOUISIANA: New Orleans, May 4. Sec., Homeo. Bd., Dr. F. H. Hardenstein, 702 Machesa Bldg., New Orleans.

MINNESOTA: Minneapolis, April 6-8. Sec., Dr. Thos. McDavitt, Lowry Bldg., St. Paul.

MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, Power Bldg., Helena.

NEVADA: Carson City, May 3. Sec., Dr. Simeon L. Lee, Carson City.

NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. R. E. McBride, Las Cruces.

NEW YORK: New York, Albany, Syracuse, Buffalo, May 18-21. Assistant, professional examinations, Mr. Herbert J. Hamilton, Education Bldg., Albany.

OKLAHOMA: Oklahoma City, April 13-14. Sec., Dr. J. M. Byrum, Shawnee.

WEST VIRGINIA: Charleston, April 13. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

INDIVIDUALISM IN MEDICAL EDUCATION

ALBERT C. EYCLESHYMER, PH.D., M.D.

Professor of Anatomy, Head of Department and Dean, University of Illinois College of Medicine

CHICAGO

Herbert Spencer well says: "There cannot fail to be a relationship between the successive systems of education and the successive social states with which they have coexisted." During the past half century our natural resources and varied industries were attracting the master minds of our country. The commercial spirit had extended into practically all lines of endeavor. It is therefore not surprising that the medical schools became strongly tinged with commercialism. In describing the medical schools of a half century ago, Flexner says that they were essentially private ventures, money making in spirit and object. They arose in small towns almost in the heart of the wilderness. Wherever or whenever the roster of untitled practitioners rose above half a dozen, a medical school was likely at any moment to be precipitated. Income was simply divided among the lecturers, who reaped a rich harvest besides the consultations which the loyalty of their former students threw into their hands. "Chairs" were variable in value, their prices varying with what was termed their "reflex" value. It might be added that the chair of principles and practice of medicine would bring two or three thousand cash; that of natural history, not a cent. Appointments rested on financial rather than educational qualifications. The professor was a busy practitioner who worked day and night. Although often exhausted, he must be ready to take his hour at the medical college. His personal experiences furnished the storehouse from which he extracted his lecture; and these experiences were beyond controversy. The students were not well enough trained to be thrown to any degree on their own resources. The country demanded for the most part but one type of physician and that type was the all round practitioner. He was obliged to know something of medicine, surgery and obstetrics, together with the specialties, including dentistry and pharmacy, and in addition to these he was expected to show proficiency as a veterinarian. In short, the medical school consisted of a group of teachers with no time to think, and a group of students who could not think, trying to satisfy a public demand for the all round physician.

The conditions today are quite different. The students are better trained, and as a group they no longer desire to be all round practitioners. They realize that the field of medicine, like other fields of endeavor, has expanded so enormously that specialization alone leads to eminence and signal success. The public does not demand the all round practitioner as it did a half century ago. The demand has decreased almost in direct proportion to the improved means of intercommunication and transportation. At present the country practitioner restricts his work largely to the more common diseases and first aids. The more obscure cases he refers to specialists who have hospital facilities at their command. Hospitals are being built over the country, and with them comes the organization of the hospital staff which, in turn, forms the basis of the group clinic. Instead of the general practitioner making a complete diagnosis, there is now a group of collaborating clinicians, each of whom is an expert in his particular field. The rapid development of the group clinic is creating a demand that must be met by the medical schools.

The conditions of half a century ago were met by the fixed curriculum, but this principle has been projected into the medical schools of today. Our national organizations dealing with medical education have recognized and emphasized the need of individualism, but have not adopted measures that materially assist the medical schools in developing the individual. The fixed curriculum is so deeply rooted, so widely spread and so thoroughly fostered by educational institutions that standardizing agencies like state examining boards are rapidly adopting or creating such curriculums as the basis for medical licensure. The day is not far distant when the schools must either incorporate in their curriculums the particular requirements of each state examining board or find that their graduates are not qualified to practice in these states. To incorporate these requirements means not only the further specification of subjects and allotted time, but also a material expansion of the curriculum. The schools are thus approaching an impasse of their own creation.

In building a medical curriculum, we should ever be mindful of the fact that no two students are alike. In the high school the student feels his way through a large range of group electives, and often before entering college he has decided that he will major in agriculture, engineering, law, theology or medicine. In his college work, electives have enabled him to accentuate his choice or perchance to find that his predilection was wrong. In both high school and college the student may have inclined toward subjects involving manual training and thereby have acquired keenness of touch and dexterity, or toward music, cultivating the sense of hearing. He may have elected biologic sciences, accentuating observation. He may have turned toward mathematics, physics and chemistry, emphasizing precision in deduction and experimentation. He may have laid special stress on languages or history, thus acquiring an excellent memory, or perchance on philosophy, thus developing the power of abstract thought.

Those of us who come in contact with beginners in the study of medicine are impressed by their differences in energy, training and ability. One student is always on time, another is always behind time; one works quickly, another slowly; one is deft, another clumsy; one student retains best what he sees—his memory is visual; another retains best what he hears—his memory is auditory; still another remembers best what he reads—his memory depends on word associations. One mind stores up isolated impressions and facts—it is analytic; another arranges impressions and facts in groups—it is synthetic. Will the student who is slow and clumsy ever make as efficient a surgeon as the one who is quick and deft? Will the one whose memory is auditory, or depends on word association, ever succeed in surgery as well as

another—who is able to visualize the positions and relations of organs in the body? Will the student who has an untrained ear ever make as efficient an internist as the one whose keenness in sound perception and discrimination enables him to differentiate between normal and abnormal sounds in the lung or heart? Is the one with an analytic mind as capable of interpreting a syndrome as another whose mind is synthetic? It is beyond question that the men who enter the medical school at the age of 22 or 23 years are quite unlike in their mental equipment; but in entering the medical school with a fixed curriculum they are beginning a four-year program that requires all students to do the same kind and the same amount of work at the same time and in the same way. It follows that the more uniform the special senses and intellectual processes, the more efficient becomes such a curriculum. To reach its maximal efficiency we must revamp and equalize the special senses and intellectual processes—but is this education?

What we should do is to determine the special assets of each student at the time he enters the medical school, and ever keep in mind his adaptability for certain kinds of work. As soon as possible we should help him to place his assets where they will yield the greatest returns. Experience teaches that most students, at the end of the second or third year of the medical course, have decided whether they wish to lay equal emphasis on medicine, surgery or obstetrics, fitting themselves for general practice, or to give special emphasis to one, fitting themselves for a special field. If, in the judgment of the faculty, the student's selection is wise, he should be permitted to follow his choice. In the fourth year the student should be allowed a further latitude which will permit him to accentuate the all round training in medicine, surgery, or obstetrics, or to lay further emphasis on one of these. In the intern year, he may further accentuate his choice by rounding himself out for general practice or by adding to his special training.

While the curriculum of each school is extremely rigid, a comparative study of curriculums shows wide variations in the different schools. One covers a total of 4,500 hours, another 3,500; anatomy is given 750 hours in one school, in another, 450; physiology 300 in one school, in another, 150; pathology, 500 in one, in another, 200; medicine 600 in one, in another, 300; surgery 600 in one, in another, 400. The amount of time given to the various subjects varies with the point of view and enthusiasm of the teacher, and with the equipment and material available for study. One school is favorably situated for the study of tropical diseases; another is able to utilize a great tuberculosis sanatorium; another, a great psychopathic institute. It thus comes about that the curriculums are extremely variable, not only in the total number of hours but also in the number of hours given to the various subjects. The recognition of variability in different institutions concedes the principle of variability within each institution.

In each department of the medical school an active fermentation is going on, with the splitting off of new segments. Just as physiology and pathology split off from anatomy, so biochemistry is outgrowing physiology; bacteriology is asserting its independence of pathology; pediatrics and neurology, otolaryngology and ophthalmology are attaining independence from general medicine and surgery. Again, there is going on a continual importation of subjects from the outlying fields of investigation. Immunity, roentgenology and parasitology have been brought into the curriculum from these outlying fields. The school that is the most actively engaged in the exploration and the investigation of borderland subjects finds the greatest difficulty in holding to a fixed curriculum.

Some twenty years ago, in a remarkable and prophetic article on "Liberty in Medical Education," the late Professor Mall¹ wrote:

The great complaint of the good student is coercion. Reared in a free atmosphere, accustomed to great liberty during his college years, he enters the medical school with intellectual slavery staring him in the face. The faculty trust is so powerful that if the student asserts his citizenship and remains away from a stupid course or one useless to himself he may be deprived of his degree. Long after he graduates he awakens to see that it is all a sham, and this fact adds another disgrace to our medical schools. We all know that students are very unequal in ability, as well as capacity for work, and why should they all pursue the same course of study? We cast out the weak and disgrace them, the mediocre continue along the trodden path, but the strong are retarded. We do wrong when we disgrace the weak, and it is our duty to develop the strong. It is poor logic and begging the question to assert that the German student develops better under the banner of liberty than the American would. It is not difficult to obtain overwhelming authority in favor of liberty in higher education; it is only degrading to our profession in America to assert that our students are not worthy of it. As long as this continues, medical education in America, in spite of the advance it has made during the last twenty-five years, will remain at its present low level in the eyes of the educators of the world.

The curriculum in the accompanying tabulation, as given and advocated by Professor Mall, might well serve as a basis on which the medical schools of today could build elastic curriculums.

MEDICAL CURRICULUM*

PRECLINICAL SUBJECTS		
	Obligatory	Elective
Anatomy	6 units	15
Physiology	2 units	4
Physiologic chemistry and pharmacology	3 units	6
Pathology and bacteriology	4 units	10
Hygiene and bacteriology		10
Elective	9 or more	
24 = two years' work		
CLINICAL SUBJECTS		
Medicine	6 units	15
Surgery	5 units	15
Obstetrics	3 units	5
Gynecology		5
Dermatology		4
Pediatrics		4
Nervous diseases		5
Genito-urinary diseases		4
Laryngology		4
Ophthalmology		5
Medical jurisprudence		2
Psychiatry		4
Elective	10 or more	
24 = two years' work		

* The curriculum extends over a period of four years and comprises about 3,000 hours. The unit is the equivalent of from 60 to 65 clock hours.

Professor Mall said:

In the above table I have arranged the units in two columns, reducing the obligatory courses to their minimum without excluding any of the seven branches. Further cutting-down might be an improvement, but I will not raise that question at present. As it stands in the table, 60 per cent. of the entire four years is obligatory, and the remaining 40 per cent. of the work is to be selected from a large group of elective courses. As they stand in the second column it would require an average student eight or ten years to take them all, and the two columns together represent work which our best schools can easily give at the present time. Much of our whole trouble in teaching is that we are trying to put ten years' work into four. . . . Each student might try a different combination while working out his own salvation and developing his individuality. The weak student would either drop out or go slower, the average would follow the trodden path, the good one would develop himself.

I have quoted Professor Mall in particular because he has demonstrated through his students the soundness of his views on academic freedom. There is only one way to develop strong men, and that is by helping them to become independent thinkers. Electives are the stepping stones to independent thought, and independent thought is the threshold of knowledge. We cannot keep the medical students marching in the trodden paths of their predecessors until weary and heart-sick they complete the march, only to find that they have also acquired mental debility on the way. We must tear down the restraining walls, and encourage them to forsake the trodden paths and to explore the unknown fields. We must help them to realize that the laws governing health constitute a limitless expanse for exploration, and that on our knowledge of these laws rests the physical efficiency of mankind.

Book Notices

MANUAL OF TROPICAL MEDICINE. By Aldo Castellani, C.M.G., M.D., M.R.C.P., Lecturer at the London School of Tropical Medicine, and Albert J. Chalmers, M.D., F.R.C.S., D.P.H. Third edition. Cloth. Price, \$12. Pp. 2436, with illustrations. New York: William Wood and Company, 1920.

The first edition of this book, published in 1910, contained 1,242 pages. This edition contains 2,436. This may well be regarded as an index of the growth of our knowledge of tropical diseases in the last decade. In contents, the book is exhaustive; in fact, well nigh encyclopedic. Its three main divisions are the introduction, Part II on causation of tropical diseases and Part III on specific diseases of the tropics. The introduction includes chapters on the history of tropical medicine, tropical races, tropical climatology, tropical foods, tropical diseases and fitness for tropical life. The section on causation discusses, under physical causes, temperature and humidity, pressure and radiation, and traumatism. Under chemical causes are considered animal and vegetable poisons, including those used in hunting, fishing and warfare, as well as poisonous foods. This section also contains three exhaustive and interesting chapters on venomous animals, including spiders, scorpions, venomous fish, and the numerous snakes of the tropics. The section devoted to tropical parasites and their rôle in the production and transmission of disease is necessarily large, consisting of nearly 800 pages.

Parasites and carriers are discussed in zoological order, as protozoa, worms, leeches, ticks, and mites, insects, animal carriers and vegetable parasites. The third part, comprising over half of the book, treats of specific diseases of the tropics, dividing them into fevers, general diseases and systemic diseases. Under fevers are discussed those carried by mosquitoes, namely, the malarias, the tropical hemoglobinurias, yellow fever, dengue and allied fevers. Diseases carried by the tsetse fly and similar insects are the trypanosomiasis and the kala-azars. Those carried by lice and ticks are the relapsing fever, typhus fever, spotted fever and tsutsugamushi fever. It is difficult to understand why Rocky Mountain fever is discussed in this connection, since the authors state that it is found only in the mountainous regions of the United States. The other fevers are unclassified or are listed as probably due to bacterial infection. One of the most interesting chapters is that on the differential diagnosis of a tropical fever in which the diagnostic symptoms are tabulated for easy reference. General diseases are divided into those with an animal causation, including frambesia, verruca, the filariases, etc.; those with a vegetable causation, as leprosy and histoplasmosis; diseases due to chemical causes, including beriberi and epidemic dropsy; and general diseases the cause of which is unknown, under which the authors classify pellagra. The last section takes up in detail the various systemic diseases peculiar to the tropics.

It is interesting to note that in spite of the attitude regarding alcohol adopted by the English, the authors take every occasion to emphasize the danger of the use of alcohol and the inadvisability of any one addicted to its use, even in moderate quantities, undertaking work in tropical countries. Even the therapeutic value of alcohol is minimized, and in the chapter on venomous reptiles a severe blow is dealt at the time honored superstition of the value of alcohol in the treatment of snake bites. "Brandy and whisky have been repeatedly vaunted but they are useless." Apparently the authors have not had access to contemporary American literature. In the references to articles on food and nutrition, the latest reference to an American article is 1911, and none is made to the work of McCollum, Osborn and Mendel in the last five years. The book is copiously illustrated, and one of its most valuable features is the list of references following each chapter. Under the section on the state and tropical diseases is a list of eighty-seven special journals on this subject and an extended list of special works on tropical medicine, its history and development. In addition to its completeness, the fact that the third edition has been revised since the war and that the authors have had twenty years' experience in the tropics will justify its acceptance as one of the leading English authorities on tropical diseases.

Social Medicine and Medical Economics**THE VIRGIN ISLANDS OF THE UNITED STATES**

B. V. MCCLANAHAN, M.D.

GALESBURG, ILL.

Exactly one week prior to our declaration of war on Germany, the United States took over certain islands of unquestioned value in the neighborhood of Porto Rico. From a naval standpoint these islands possess marked strategic features, the most important of which probably is the landlocked harbor of Charlotte Amalie, St. Thomas. From a public health and medical point of view these most recently acquired possessions also present some very interesting phases.

The Virgin Islands of the United States (formerly the Danish West Indies) consist of a group of some fifty small islands, near the juncture between the Atlantic Ocean and the Caribbean Sea, lying from 30 to 80 miles east and south of Porto Rico. They were acquired from Denmark, March 31, 1917. From a period of a few years prior to this date the former government had been allowing the islands to decline gradually, the United States having tried twice before to gain control. Since their acquisition they have been under the control of the Navy Department, and it appears proper that they should so continue, as their small size necessitates their dependence on naval life and the sea for their welfare.

Commander (now Captain) C. S. Butler, Medical Corps, U. S. Navy, and I were the first American medical officers to reach the islands following their transfer. Arriving at Charlotte Amalie, the principal harbor of the island of St. Thomas, April 21, 1917, Dr. Butler remained for duty on St. Thomas, and I was detailed for both military and civilian duty to Christiansted, St. Croix.

The gradual decline under the former government was decidedly accelerated by a destructive hurricane in October, 1916, in which Christiansted suffered severely. Its hospital buildings, which were situated on a hill, were almost completely demolished and rendered wholly uninhabitable. Instruments, beds, linen and much of the original equipment were strewn over a wide area and rain-soaked beyond hope of further use.

The building occupied by the hospital on my arrival was an old chapel, of which the rostrum and mahogany railings still remained. A table near the pulpit served as office for both physician and nurse, and the medicine locker consisted of an old clothes press formerly used by the minister. In the center of the chapel a partition, reaching half way to the ceiling, had been erected, thus dividing off a space into a men's ward and a women's ward. This building, together with another about half a block away, were all that were ceded to us when I received control of the medical situation at Christiansted.

MEDICAL STATISTICS

The islands—and I speak principally of St. Croix, the largest and with the possible exception of harbors the most important one of the group—as we found them were in dire need of active medical, surgical and sanitary aid. Their welfare centered naturally around their health, and this was greatly impaired. Approximately 95 per cent. of the population were black. Statistics collected by former Danish physicians indicated that the majority of the negro population had venereal disease; about 50 per cent. had syphilis in either congenital or acquired form. Filariæ were present in the blood of from 15 to 25 per cent. of individuals examined, and over 5 per cent. of the adults had elephantiasis in some form. Leprosy, considering the population of the islands, was preva-

lent, there being from sixty to ninety inmates in the asylum during the first two years of our occupancy, while the total population of the islands was less than 28,000.

Typhoid fever was never troublesome, appearing only sporadically over the islands. The last severe epidemic occurred over two generations ago; but to prevent any further trouble from this source the entire population of the islands was given antityphoid vaccine during the latter part of 1918. Malaria was rare, although the anopheles mosquito was found often in collections gathered. Yellow fever and bubonic plague had been unknown for the last hundred years, while pellagra was present in a goodly percentage of the hospital cases treated.

Probably one of the greatest scourges of this small country was the high infant mortality. Fifty-one per cent. of the children died before reaching the age of 3 years and about one half of these before they were 1 year old. This high infant mortality rate may be explained by two factors: illegitimacy and the tropics. According to the United States census taken in 1918, nearly 65 per cent. of the parents living together were not legally married, and in relationships of this kind, combined with the inherent lassitude of the tropics, it naturally rested with the mother to support the children. The second contributing factor may be said to be the tropics themselves; milk, of course, soured readily, and like all food-stuffs was hard to obtain in anything like a clean state. This, combined with a lack of feeding knowledge and neglect, caused infant gastro-intestinal infections to reach a high mark.

It is safe to say that at the time of American occupation 35 per cent. of the population of the islands needed medical or surgical care of some sort. Syphilitic conditions were present, some of which disappeared like magic under the proper treatment. Venereal sores, bathed continually in pus and filth and often aggravated by edematous foreskins, were prevalent. We encountered many hydroceles containing a quart or more of fluid, hernias of enormous size and, last but by no means least, elephantiasis extremities and scrotums of such size and weight that they not only impaired the general health but served as an extremely cumbersome barrier to locomotion.

PHYSICIANS' FEES

The question of fees charged prior to American occupancy is one of especial interest. The physicians to the islands were sent by the Danish government and received ample salaries from their home government. On the other hand, the ordinary negro inhabitant of the islands had limited financial means so that charges of from one to ten dollars for major operations, while appearing exceedingly small, were really reasonable and just. The price for a herniotomy was five dollars, and the highest price charged for any operation was twenty-five dollars. These prices, of course, were for the negro population which could not well afford to pay more. Well-to-do planters, sugar factory operators and plantation owners were charged more than the stipulated rates at the discretion of the physician. Contract work was practiced generally with the larger estates and sugar factories, these contracts calling for one or two visits of the physician at the factory and laborers' villages weekly, with visits more often during the sugar crop time.

HOSPITALS

As I have mentioned, the hurricane of 1916 wrought havoc especially to the hospital at Christiansted. The other hospitals of the islands situated at Charlotte Amalie, St. Thomas and at Frederiksted, St. Croix, suffered less and were able to continue in the same buildings. The buildings occupied temporarily by the Christiansted hospital would hardly accommodate sixty-five patients, were in no sense suited for

the care of the sick, and had been barely made fit by the installation of crude plumbing, tin flooring in the operating room, kerosene lamps, and other absolute necessities. The hospital boasted two private rooms, which were private, however, only in the sense that they contained one bed each. In no other respect were they private, for they had windows that opened on a hallway, partitions that reached only half way to the ceiling, and both directly adjoined the children's ward.

Rigid iron beds which could not be taken apart and with a series of crossed iron bands for springs were what comprised the resting place for the patients in the hospital. Mattresses were made of horsehair or seaweed, pressed hard and thick. Bed linens, towels and other napery were of a heavy linen of good grade, all sent from Denmark; and with the exception of being heavy, cumbersome and unpliant, they were very fine.

FACILITIES FOR SURGERY

The operating room consisted of an east room on the second story, with a tin floor, an antique operating table, and locally constructed sinks, stands and instrument cabinets. It was lighted for night work with two large round-burner kerosene lamps. One naturally feels a trifle uncomfortable at the thought of operating under an open flame; but by using extreme caution we were able to care for the small amount of night emergency surgery that was necessary.

The instruments in the operating room were mostly of Danish origin, some of them peculiar and clumsy; but they served their purpose very well. These instruments, in addition to the ones furnished with the Navy supplies for Marines, gave us all we really needed for most of the surgery encountered. Suture material was scarce, the supply of catgut being particularly low; and as this article was hard to obtain, we were continually handicapped by the lack of it.

Surgical dressings, sponges, cotton, binders, pads, and the like were all sent out from Denmark where, it was said, they were made under the direction and supervision of the queen herself. However true or untrue this rumor may have been, it was a fact that, prior to our occupancy, yearly and oftener, if necessary, the queen would send out large quantities of surgical supplies all wrapped, sealed, labeled and sterilized ready for immediate use. A fair amount of this surgical material was on hand when we arrived.

The needles in the operating room were not of the type we had been used to; and because all metal rusts so easily in the tropics, these needles were of little value. The Christiansted hospital was indeed grateful for the gift of assorted operating needles sent to them by a Chicago hospital on realizing actual conditions.

The majority of the surgery had to be done without the use of rubber gloves, not as a matter of choice, but because the hospital had only six pairs of its own. We literally wore gloves to keep our hands clean instead of for the protection of the patient from infection, and considering our handicaps, we had comparatively few infections.

We were unable to do all the surgery that was continually at hand. We did all the surgery we could, considering the size of the hospital and the limited amount of supplies available. At best, it was a slow process, as all sterile water, instruments, etc., had to be prepared over small charcoal pots in the corridor adjoining the operating room.

PROSPECTS IN THE FUTURE

I left the islands in March, 1919, and many improvements were well under way and progressing even before this time. The American Red Cross made some liberal and beneficial donations to the hospitals of the Virgin Islands during 1918. The Christiansted hospital also received at this time a complete roentgen-ray outfit and a motor ambulance. Repairs

were effected, among them the installation of electric lights, which greatly increased the efficiency of the institution. Dispensaries for outpatients had been established at all hospitals in the islands, and a great deal of good was being done in the treatment of ambulatory cases. An earnest attempt had been made, combined with the efforts of the department of health, to ascertain and treat all venereal cases, trying if possible to get at the source of infection in every case.

The future health of these islands, and in this way the real future of the islands, depends largely on the work and the cooperation of the medical men stationed there. With the wealth of material to work on, especially surgical, duty was a pleasure to me, and I am sure that all the medical officers felt grateful for the opportunity to serve in so new, rich and fertile a field.

249 East Main Street.

Medicolegal

Time of Liability of Physicians and Surgeons

(*Bowers v. Santee (Ohio)*, 124 N. E. R. 238)

The Supreme Court of Ohio, reversing a judgment affirmed by the court of appeals that sustained the defendant's demurrer to the plaintiff's petition, says that the petition stated that, Dec. 29, 1913, the plaintiff sustained a fracture of both bones of her left leg above the ankle joint and employed the defendant to treat the case, that he was unsuccessful in his first attempt to reduce the fracture, and in about a week attempted again to set or reset the fractured limb, and again negligently failed to place the fractured ends of the bones together, etc. This action for damages was begun in April, 1915. The defendant's demurrer was on the ground that the plaintiff's right of action was barred by the state statute of limitations, and the question was, When did the latter begin to run as against the plaintiff? Did more than one year intervene between the date on which her cause of action "accrued" and the date on which such action was commenced? The supreme court holds that, in an action for a breach of contract in such a case, the statute of limitations does not begin to run until the contract relation is terminated, and that, under the allegations of the plaintiff's petition that the contract of employment between the surgeon and his patient continued from Dec. 29, 1913, to May, 1914, the plaintiff's right of action did not accrue until May, 1914, and was not barred by the statute of limitations when the action was brought.

The first two paragraphs of the syllabus in the case of *Gillette v. Tucker*, 67 Ohio St. 106, 65 N. E. 865, are as follows:

1. A surgeon and physician, employed to treat a case professionally, is under an obligation, which the law implies from the employment, to exercise the average degree of skill, care, and diligence exercised by members of the same profession, practicing in the same or a similar locality, in the light of the present state of medical and surgical science; and that he will indemnify the patient against any injurious consequences which may result from his want of ordinary skill, care, and attention in the exercise of his employment.

2. It is the duty of the physician and surgeon to exercise due and ordinary skill, care, and attention, not only in and about an operation which he decides to be necessary, but also, in the absence of a mutual understanding, or notice to the contrary, to render such continued further care and treatment as the necessity of the case requires; and he is liable for injuries and damages which proximately result from the want of ordinary skill, care, and attention.

The doctrine announced in these two paragraphs is very plain and practical, so that both surgeon and patient will have their respective interests abundantly safeguarded. The doctrine is promotive of the exercise of reasonable skill, care, and treatment by the surgeon, not only at the specific time of the operation, but also during the subsequent period of treatment necessary to a reasonable and substantial recovery. The patient relies almost wholly on the judgment of the surgeon, and under the usual circumstances of each case is bound so to do; and if the injury is not reduced,

and a normal condition restored, as fully or as speedily as expected, the patient is still at liberty to rely on the professional skill, care and treatment to complete such recovery so long as the surgeon continues his employment with reference to the injury. The decision in *Gillette v. Tucker* was by a divided court that stood 3 to 3, with a rather vigorous dissenting opinion which was followed a few years later in *McArthur v. Bowers*, 72 Ohio St. 656, 76 N. E. 1128; but this court now disapproves the *McArthur* case, and approves and reaffirms the doctrine announced in the *Gillette* case. Physicians and surgeons exercising reasonable care and skill need have no fear of it. Reckless and careless physicians and surgeons should be kept in fear of it.

The law should not impose on the patient a duty that he can know only through expert knowledge which he does not possess, but as to which he is compelled to accept the judgment of his physician or surgeon. Moreover, it is clearly just to the surgeon that he be not harassed by any premature litigation instituted in order to save the right of the patient in the event that there be substantial malpractice. The surgeon should have all reasonable time and opportunity to correct the evils which made the operation or treatment necessary, and even reasonable time and opportunity to correct the ordinary and usual mistakes incident to even skilled surgery. The doctrine announced here is conducive to that mutual confidence that is highly essential in the relation between surgeon and patient.

Examination Required to Determine Injury to Eye

(*Holton v. Janes (N. M.)*, 183 Pac. R. 395)

The Supreme Court of New Mexico holds that, in a personal injury case in which the plaintiff had voluntarily exhibited an injury to his head to the jury for inspection, and the defendant moved that the court compel the plaintiff to submit to a physical examination of his head by physicians named by the defendant, it was error to deny the defendant's request. The supreme court says that an examination of the cases will show that the courts have uniformly held that, when a plaintiff in a personal injury suit voluntarily exhibits the injured part of his body to the jury for inspection, the portion of his body so exhibited becomes an exhibit in the case, like any other object or thing introduced in evidence, and the opposite party has the right to make such inspection of it as will enable him to explain, criticize or impeach its value as evidence, and to that end have it examined by experts. As to the wounds in his head, the plaintiff in this case alleged that they greatly injured and weakened his eyesight, making it difficult for him to discern objects at any considerable distance. It is a matter of common knowledge, of which courts will take notice, that the question of the impairment of vision is capable of exact demonstration by expert examination, and in this case, when the plaintiff put his head in evidence and permitted the jury to examine it, unless the eye which he complained of as being injured was put out, the jury could in no manner determine the extent of the injury to it, if any, but with the aid of experts the matter was capable of exact determination. For these reasons this cause, wherein the plaintiff recovered a judgment, is reversed and remanded with instructions to award the defendant a new trial.

Privilege Not Affected by Services Being Gratuitous

(*In re Hallenberg's Guardianship (Minn.)*, 174 N. W. R. 443)

The Supreme Court of Minnesota holds, in a proceeding to determine the competency of a man 82 years old to care for and manage his property, that the rule as to privileged communications applied and that there was no error in excluding the testimony of a physician as to consultations with the man in regard to certain ailments, when the only ground on which it was sought to sustain the admissibility of such testimony, in the face of the express provisions of the statute to the contrary, was that the physician was the patient's son-in-law and did not expect pay for his services. The application of the rule does not depend on the services being gratuitous or paid for.

ANNUAL CONFERENCE ON PUBLIC HEALTH AND LEGISLATION

Held under the auspices of the Council on Health and Public Instruction of the American Medical Association, March 4, 1920

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich., in the Chair.

Chairman's Address

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich.: There has never been a time when so many people were interested in public health as at present. National health associations specially interested may be divided into official and voluntary. The federal Public Health Service arrested bubonic plague and held it in abeyance at a total cost of between 200 and 300 lives on the Pacific Coast, when it might have spread all over this country. Splendid work has been done on pellagra. Its etiology has not been settled, but the work of Goldberger and his associates on the influence of diet on pellagra is a wonderful demonstration. The laboratory work of the Public Health Service, the testing of animal products, the research work on typhus fever, and anaphylaxis are among the most valuable activities of the United States Public Health Service. But the federal government cannot go into a state and do health work, unless requested by the state to do so. The exercise of medical functions, whether the regulation of medical practice or preventive medicine, is under state control, and I think it is rather fortunate that this is the case, because, divided as we are into forty-eight political groups, we do not have to make the same experiments at the same time. Other organizations of officials I might mention are the Conference of State Health Officers and the American Public Health Association. No better work is being done anywhere than by the International Health Board. We all know the splendid work the Red Cross did during the war and the admirable support received from the people. The Red Cross found itself at the end of

the war with a great organization. With thousands of nurses, hundreds of medical officers, with millions of dollars, and plenty of work to do in Europe, the Red Cross is continuing to do that work in a most splendid way. The National Tuberculosis Association, founded in 1904, has continued to expand, and receives its revenue from the Christmas sale of stamps, which last December amounted to \$4,200,000. The Association for Social Hygiene is a national organization interested in venereal or so-called social diseases, and just now there is a great deal of enthusiasm being displayed in reference to this work. The child welfare movement is more or less mixed up with the health crusade under the management of the National Tuberculosis Association; but as long as the children are getting the benefit, it does not make any difference where the aid is coming from.

Report of the Secretary

DR. FREDERICK R. GREEN, Chicago: This is the first Conference on Public Health and Legislation called by the Council on Health and Public Instruction since Feb. 6, 1917. The absorption of the public and the profession in the war rendered it inexpedient to hold a conference in 1918 or 1919. Owing to the activities and lessons of the war, the attitude of the public toward health matters is today entirely different from that of five years ago. The public health movement is rapidly passing out of the propaganda stage and is entering the constructive period. What the public wants to know today is how diseases can best be prevented and efficiency maintained at the highest point. The duty of physicians, both as individuals and as organizations, is to furnish plans for the development of governmental health agencies for each of our political units from which can be constructed the best type of organization for health conservation.

One of the greatest possibilities for usefulness in the annual midwinter conference is the opportunity which it offers for concentrating at one time and place many of our meetings and independent bodies which are now scattered throughout the year. One of the most important functions of the Council has been to act as a hub around which other movements and organizations could center. If this annual conference can be made the rallying point for as many other conferences, meetings and organizations in the health field as possible, we shall be able to secure greater effectiveness at a diminished cost, which is the essential problem of all administration.

Standardization of Public Health Activities

DR. GEORGE E. VINCENT, New York: This paper will appear in full in an early issue of THE JOURNAL.

The Standardization of State Public Health Organizations

DR. CHARLES C. CHAPIN, Providence, R. I.: When we talk about standardizing public health work we mean about what the manufacturer means by standardizing his workshop. We mean that health officers should be encouraged to adopt the very best and latest methods, and that the retention of obsolete and useless methods should be discouraged. Accepting this definition of standardization, we ask: What are the means best calculated to promote the desired improvement in the public health work of the states? Every health officer would like to improve his service. There are two main reasons why he does not do more: he does not know what to do and he has not the funds wherewith to do it. There are a lot of people who will disagree with me because I am inclined to place the greater importance on the former. The first step is to show him what others are doing and what he can and should do. One important means of standardizing state health work is to show what is being done in every state, and analyze and arrange the data so that the facts may be easily found. This is no small task, and is impossible without the assistance of the state health officers themselves. A questionnaire is a terrible thing, yet it seems to be necessary. To find what a health department is really doing, numberless questions must be asked; and to answer them correctly often requires a great deal of time and trouble on the part of a great many persons. Another important point in the organization of health work is the consideration of

relative values. It is not enough to demonstrate that the state supervision of water supplies reduces typhoid fever, that the giving of antirabic treatment prevents rabies, that the inspection of milk raises the bacterial standard, and that the operation of a sanatorium restores sick people to health. We should know, if possible, how much sickness is saved and how many deaths are prevented. Accurate accounts should be kept by every health officer of each definite line of work which he is following. One of the rarest things to find in a health office is accurate cost accounting. Uniformity in all parts of the reports of state health departments would make for economy and efficiency. Every report should contain certain standard and uniform tables of mortality and morbidity statistics. The work of every division of the department should be set forth clearly and simply, and numerical statements should be inserted whenever practicable. Much can be done to standardize and improve the work of state health organizations by a survey of their activities with a comparison of costs and results. The results of the survey should be widely distributed, and the report should include a numerical rating of the states. The collection of the data would be greatly facilitated by uniform accounting and reporting. State health officers could provide for this through a committee to consider the relative importance of health activities and the standards on which a rating should be based. A survey, however, cannot well be made by state officials. It had much better be made by some agency entirely independent of them. A survey should be made periodically, perhaps every five years. Sanitary science is growing rapidly, and sanitary practice should keep pace with it. Such surveys are expensive, but before the war the states were spending annually more than \$3,250,000 for public health. The amount is far greater now. A small fraction of 1 per cent. of this would be a small sum to pay for taking account of stock.

Standardization of Municipal Health Organization

DR. ALLAN J. McLAUGHLIN, Washington, D. C.: Standardization is both feasible and desirable to standardize "objectives" in municipal health work; but standardization in detail of methods of procedure is extremely difficult, and in many instances may be undesirable. Fundamentals in public health work are the same for all cities, and these may be standardized. These are the factors in the public health problem which are common to all cities. Standardization by an authoritative agency will be of inestimable value to the health officer in having charged to other departments the cost of the indirect health activities which are often paid for out of health appropriations. In initiating new work, standardization will be of great assistance, but its greatest aid will often be the demonstrations made by voluntary unofficial agencies. Thus, in standardizing health departments, which really means reorganization of health departments, the voluntary and unofficial agencies engaged in health work must be considered and their activities utilized to cover gaps in the official campaign. What are the aims of an ideal health department and the objectives which it seeks to attain, and what are the fundamentals of organization? The aims of health departments are the eradication of preventable disease, the elimination of corrigible physical and mental defects, and the maintenance of all individuals in the best possible physical and mental condition. In carrying out these aims we have as objectives the prevention of infant mortality, the prevention and correction of physical and mental defects in the child, and the prevention of preventable diseases. To accomplish these aims and to obtain these objectives we must consider these fundamentals in our health machine: administration, vital statistics, child hygiene, industrial hygiene, communicable diseases, public health education, sanitary engineering, food inspection, hospitals and sick relief. Standardization of the fundamentals of organization can be effected on a nation-wide basis, and a committee on standardization could formulate the general classes of work which should be undertaken in every municipal health department. An example of the value of such standardization is the possibility of securing epidemiologic data in usable form, by a proper employment of the vital statistics division, and the regular

field force of the department. The committee on standardization can make very useful recommendations for the transfer of much of the work of abating nuisances, and the collection and disposal of garbage and refuse to other departments; but here again local conditions will determine how best to adjust the work in each city. The greatest single defect in municipal health organization today is the lack of machinery for coordinating and utilizing voluntary and unofficial agencies in an official plan to insure teamwork.

DISCUSSION

DR. C. ST. CLAIR DRAKE, Springfield, Ill.: My own conception of standardization is the development throughout the nation of health department machinery to the highest point of efficiency consistent with the law; along uniform lines which will permit the best coordinative functioning with all governmental and extragovernmental health agencies; with an internal arrangement of bureaus or divisions which will make possible the highest degree of cooperation with the minimum of duplication of effort. I naturally view this question from the standpoint of the state health officer. Any acceptable form of standardization must take into consideration these fundamental points: (1) a definition of what constitutes public health work; (2) definite knowledge of what all other states are doing and of the type of machinery employed by them; (3) the adoption of a definite policy of relationship to other states' health departments, to the federal government, to local health authorities, to extragovernmental health agencies and to the public at large; (4) the determination of the functions which shall be carried out by the state health department and of those which are to be imposed on other state departments; (5) the determination of the type of organization most desirable for state health departments, and the essential divisions and bureaus and their relationship to each other; (6) the determination of a reasonable and acceptable policy in dealing with extragovernmental health agencies, and (7) the determination of the extent to which federal aid in state public health work is properly to be encouraged. Any form of standardization requires a thorough knowledge of what other state health departments are doing and how they are doing it, so that there may be uniformity of procedure. Without this knowledge, it is practically impossible to compare the different departments, to interpret their reports and financial statements, or to determine the comparative efficiency of any individual department.

There should also be developed a well defined departmental policy based on a reasonable interpretation of the law; a policy in which the law is not employed as the means of evading obligations or of passing on responsibility, and a policy which does not assume more power than the statutes actually give or more than the courts would reasonably sustain.

There is also a serious need for some definite policy as to what functions the state department of health should perform, and what functions should be relegated to other state departments.

DR. ENNION WILLIAMS, Richmond, Va.: The value of any particular public health method should be ultimately measured by the morbidity or mortality statistics, and no one would undertake to interpret the results of statistics until several years shall have elapsed. For instance, for the last three years, we have been carrying on a rather active campaign in the public schools by circularizing teachers and education work to inculcate those personal habits that would prevent the transference of mouth secretions. The statistics for two years following the introduction of this measure would indicate more than 50 per cent. reduction in deaths and in cases of scarlet fever and diphtheria. Yet I would not be willing to say from the experience of two years that this measure was or was not responsible for the reduction, and consequently its value cannot yet be demonstrated. We, therefore, cannot even compare its value with the customary methods of quarantine and disinfection, which are more costly and require greater health organizations. Thus, no numerical valuation can yet be placed on such measures; also, there is likely to be a great difference of opinion as to the value of measures until they are demonstrated by statistics.

DR. W. S. RANKIN, Raleigh, N. C.: I believe in numerical scoring, not only in interstate work but also in the work of states. We do it in dairies, and in the medical inspection of schools. I am working out a system of numerical scoring for county health departments, taking the various units, or county health problems, and all the items of work embraced in those units and giving each item and each unit a financial equipment.

DR. SAMUEL J. CRUMBINE, Topeka, Kan.: I think it is appropriate for this conference, composed of health officers and members of the medical profession, to make a request of the Rockefeller Foundation to make a survey of extragovernmental agencies. If this were done I believe it would receive serious consideration. I know of no agency better fitted to undertake that work. It would be an authoritative utterance on that question.

DR. ALLEN W. FREEMAN, Columbus, Ohio: It is essential to get all the people who are interested in this health movement to recognize the necessity of laying a sound foundation. We should strive to develop a sound sentiment for health among the people, and then build a sound structure, with competent people to run it, a decent scale of salaries, and work by an administrative system covering the whole state.

DR. HAVEN EMERSON, New York: There are three absolutely indispensable functions which should be standardized: costs, results, and the control of communicable diseases. It is the function of the Public Health Service of the United States to call the attention of state health officers and local health officers to the possibility of standardizing cost accounting for public health functions. We ought to be able to show how much it costs to carry on a certain definite function. It ought to be possible to get comparative data on specific functions in communities that have organized health departments.

DR. H. N. OLIN, Lansing, Mich.: We shall find it difficult to standardize methods of accounting. I am in favor of the standardization of public health activities. Let us know what our neighbors are doing. As commissioner of health of Michigan, I should like to know the details of the health work in Massachusetts, Ohio and some of the other states, so as to give the people of Michigan better health service.

DR. FRANK BILLINGS, Chicago: I want to speak on two points. First, the need of publicity to educate the people, which is one of the reasons the American Medical Association organized its Council on Health and Public Instruction. There are approximately 80,000 members of the American Medical Association, representing the best elements of the medical profession of the country. They are interested in health and in the prevention of disease. The central office has a card index, not only of every member of the association, but of every physician in the country. Probably there is no other body of men in the country with the facilities of communication not only with organized county and state societies but also with individuals who are interested in health matters. Second, in taking up the matter, the American Medical Association had no thought of dominating the field of health, but at the time the Council on Health and Public Instruction was organized there was very little cooperative work with all the health agencies of the country, and its policy was to try to get together all of these health agencies for the purpose of concentration of effort and teamwork. I believe it has done a vast amount of good in that respect.

DR. RACHELLE S. YARROS, Chicago: The state and local boards of health have tried to enforce measures that the people do not understand. If we expect support from the people we must educate them as to what we really want. State and local boards of health should also educate physicians because many of them do not understand what we are aiming at. If we educate the people, we shall get their support.

DR. S. W. WELCH, Montgomery, Ala.: All public health work must be done by governmental agencies. We must have something around which voluntary agencies can be coordinated; and until we have a county health organization, which takes in the county as a unit, and around which can

be collected and directed the activities of the general public, we are not going to get anywhere in that community. County organizations should function with the state organization.

DR. HENRY VAUGHAN, Detroit: We ought to have some centralized place where the vast amount of information collected from the different health departments throughout the country can be made available to local and state health departments. I should like to know something of the details of venereal disease control and the measures that are carried out in different parts of the country. To do that a questionnaire can be sent to every local or state health officer in the Union.

DR. GEORGE E. VINCENT, New York: If the Rockefeller Foundation were asked to cooperate in such an undertaking as that mentioned by Dr. Vaughan of collecting information. I am sure its board of trustees would be willing to cooperate with some representative agency that stood before the public authoritatively for whatever it did; and if a constructive cooperative program, based on the requirement of information and cooperation with individual state departments in building up their work, were carried out, it would be very carefully and sympathetically considered by the board of trustees of the Rockefeller Foundation.

DR. CHARLES V. CHAPIN, Providence, R. I.: It would be a good plan for somebody to make such a survey as we have been discussing. Many state health officers desire to have such a survey made. As to uniform reports of accounts, I believe that of very great importance; but I am afraid many health officers do not realize the tremendous importance of it.

(To be continued)

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Joint Annual Conference of the Council on Medical Education of the American Medical Association with the Association of American Medical Colleges and the Federation of State Medical Boards of the United States, held in Chicago, March 1-3, 1920

(Continued from page 913)

Report of Committee on Public Health and Preventive Medicine

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich.: The trend and spirit of medical schools is toward curative medicine. The graduates of our best medical schools today are not fitted to do public health work. The committee recommends that an improvement be made in this direction. During the last two or three years the National Board of Medical Examiners, examining graduates from Class A schools only, and the very best graduates of those schools, has scarcely found men who could get a passing mark in preventive medicine, although there have been excellent marks in surgery, medicine and the specialties. It is a matter for consideration whether the medical profession should fit men for preventive medicine or turn the job over to somebody else. The sanitary engineer as an all around man is better fitted as an epidemiologist than the average physician. A number of medical schools are now offering courses in public health. They have had a very precarious existence. The best public health courses are given at Harvard and at the Johns Hopkins schools, and in neither of these places is the attendance large enough to justify the existence of the school. The regulations of most of the states and many municipalities have been changed so that a medical degree is not required for health officers. Some of the best municipal health commissioners today are not physicians. In our opinion the tendency in all medical schools is to teach curative medicine, not prevention. The committee recommends that we insist that medical men who are fitting themselves for health officers should take an additional course of not less than two years. Even to make proper medical men we need more hygiene and preventive medicine in the medical course than we have. We recommend that five hours a week for one year be devoted to preventive medicine—double the amount of time we are now giving to this branch—and we do not expect to make expert

epidemiologists in this way, but possibly we can give what the ordinary practitioner needs.

DISCUSSION

DR. ALEXANDER C. ABBOTT, Philadelphia: The University of Pennsylvania in 1906 offered the first course leading to the degree of Doctor of Public Hygiene. For four years we did not have a single applicant, but in 1910 we had one applicant. Since that time we have graduated thirty-three with the degree of Doctor of Public Hygiene, and we have given a number of certificates to persons taking special departments of the work who were not qualified for the degree. I still regard the work as being to some extent experimental. The qualifications for the degree have been that a candidate shall become a Doctor of Medicine, and that the Doctor of Medicine degree should stand for the same preliminary requirements for the degree that we now require for persons entering the University of Pennsylvania Medical School. As a result, we have had satisfactory material to work on. I should say the supply and demand will control this, and the future is safe, because I take it for granted that others, who are making an honest effort to push this thing, and not rush it, are in the same position that I am. I have on my desk, more or less all the time, applications for persons to fill desirable positions. The future possibility of supplying the demands is daily growing larger.

DR. EUGENE F. McCAMPBELL, Columbus, Ohio: At the Ohio State University we started several years ago to give a course in preventive medicine. For four years, we had a cooperative course with the state department of health. The work in preventive medicine covers the situation well. In the Ohio State University we give a course in personal hygiene in the first year in medicine. The course in clinical medicine, in which epidemiology and communicable diseases come into play, is given in the junior year. The senior year is covered by a course in preventive medicine of only two hours. I think the five-hour course referred to by Dr. Vaughan is probably adequate for the medical student, except for those who desire to enter the field of industrial medicine. Opportunities for election should be given in the junior and senior year, particularly in the senior year, for intensive study of public health work. The demand far exceeds the supply. In the state of Ohio, large commercial concerns are asking for young medical men trained in public health work, particularly in preventive medicine, industrial medicine and surgery, etc., and it is impossible to supply properly trained men.

DR. JOHN SUNDWALL, Minneapolis: Public health workers in the future should be in largest measure recruited from members of the medical profession. There is no question at all that sanitarians or other members from other professions are making good health officers. The same thing is true of a great many of the sciences that make up the medical profession. Many of our best anatomists have been recruited from the departments of zoology and biology. Public health in the future is going to be concerned with a great many bigger problems than those concerned with epidemiology, such as human welfare and mental hygiene. Industrial hygiene will be expanded to include all adult hygiene.

DR. GEORGE M. KOBER, Washington, D. C.: I have been teaching hygiene since 1889, and I want to make a plea in favor of the report of the committee for a greater number of hours in the curriculums of our medical schools for this branch. In our own school we give sixty hours to general hygiene, thirty hours to the etiology and prevention of communicable diseases, and fifteen hours to military and naval hygiene. I believe that number of hours devoted to these subjects is no more than sufficient to be of substantial aid to the average practitioner in the treatment of disease. The object of hygiene is not only the prevention of disease but also the improvement of health, which is a most important factor in the treatment of disease.

DR. G. CANBY ROBINSON, St. Louis: At Washington University we have a course of thirty-three hours in preventive medicine, and eleven hours of social medicine. We have considered ways and means of improving matters, and have

discussed a plan of departmental cooperation in these matters, putting one person in charge of the course, but having all the departments participate in the working out of the completed course.

DR. A. P. MATTHEWS, Cincinnati: Dr. Vaughan's recommendation was mainly along the line of epidemiology, but there is an important field in industrial hygiene and medicine, particularly the character of people engaged in these industries. The University of Cincinnati gets support in its departments of industrial medicine and preventive medicine for public health, from the business men of Cincinnati. At the suggestion of the late Dr. Holmes, a committee of business men secured money to support the department of industrial hygiene. There is undoubtedly a great possibility of the medical profession's getting in closer touch with business industries through this means.

DR. E. P. LYON, Minneapolis: I have a feeling that as more and more subjects are pressed on the medical curriculum for entrance, we shall have to do exactly what the colleges did and make a curriculum which will be more particularly elective than any school so far has done. That will mean we shall have to specialize in degrees, and certain men who are not qualified for licensure should be content to continue their fundamental preparations until they are. We might call them all doctors when they are trained on the proper basis and fitted for the work that has to be done. Or we should view the matter from the standpoint of general good.

DR. OSKAR KLOTZ, Pittsburgh: We all realize that each school has a duty to perform which differs with the situation of the school, and it is hard to apply one standard to every school. Our own situation is much like that in Cincinnati. We have certain problems in our vicinity of outlining education in which the public is interested. If we should follow the standards of the U. S. Public Health Service in hygiene we should fail in the result. We have an industrial situation that is peculiar. The ordinary individual who has had training in hygiene is hardly able to realize the extent to which the public demands attention. The standardization of departments of hygiene is very difficult.

DR. WORTH HALE, Boston: We are developing an elective system at Harvard in the study of these problems, and are permitting fourth year men to elect a course dealing wholly with problems related to public health, hygiene and industrial medicine. We do not anticipate that they will become finished products in these subjects, but we hope that a certain group of men will become interested so that they will continue further in the work which appeals to them and thus supply some of the demand that appears to be urgent.

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich.: The prime and particular object of a medical school is to teach preventive medicine and curative medicine. A school for hygiene should not be under the medical department. I hope that schools of hygiene will be open not only to medical graduates but also to the sanitary engineer, the sociologist, or to any one who is interested.

Report of Committee on Teaching of Pharmacology

DRS. A. N. RICHARDS, TORALD SOLLMANN and C. W. EDMUNDS: Pharmacology has profited greatly by the advances in medical education which have taken place in the past ten or fifteen years. New departments have been established in schools where none existed before, and where the teaching of this subject was under the control of some other medical branch, it has been split off and established as a separate and distinct department. The teaching of the subject has been simplified also through the aid of the state licensing boards, which are confining their attention in examinations to the more important drugs, to the exclusion of those of lesser importance. It is hoped and expected that these tendencies, if continued, will still further advance the teaching of pharmacology in the future. In regard to the contents of the course in pharmacology, the student should learn what the really useful drugs are, and also the limitations of their usefulness. He should learn their fundamental action and their side actions. These studies lead naturally

to a study of their toxicology and to the treatment of poisoning. He must learn sufficient *materia medica* to know something of the physical and chemical characters of the drugs and of their principal preparations, so as to be able to prescribe them correctly, and he must become fairly proficient in prescription writing. He should also be required to practice the writing of prescriptions in his later clinical courses in medicine and in therapeutics whenever an occasion for the use of drugs arises. Some instruction in therapeutics may be given, but the practical work in this branch must necessarily be left for the hospital ward.

The time to be devoted to the subject should be from 175 to 200 hours, not taking into consideration the teaching of practical therapeutics. This may be divided roughly into two parts: from seventy-six to 100 hours to be devoted to laboratory instruction, and the remainder to a systematic lecture or quiz course. The laboratory time, in turn, may be divided into two parts if desired: one part devoted to *materia medica* and pharmacy being given in the first year, and the other portion devoted to pharmacodynamics proper being given in the second year. Or, if preferred, the entire time to be spent in laboratory instruction may be utilized in one course to be given preferably in the second or third year. In this course a few hours may be devoted to pharmacy and to the chemistry of drugs, but the greatest emphasis should be laid on experimental pharmacodynamics. As far as possible, the experiments should be carried out by the students, working in groups under adequate supervision; but when the experiments are not suitable for students to carry out the work themselves, demonstrations may be substituted. Carefully kept notes of all the experiments should be required of all the students. The laboratory course should be rounded out by frequent informal conferences, quizzes and lectures, so as to give the student an intelligent knowledge of the subject under discussion. Some introductory work in the prescribing of the commoner remedies may also be given in the laboratory course. The remaining seventy-five or 100 hours to be devoted to the subject may be utilized according to the wishes of the instructor in charge, either as a lecture course with frequent quizzes or as a quiz course proper following one of the standard textbooks and supplemented by lectures on different phases of the subject. This course should follow on the completion of physiology and would, therefore, naturally come in the second year or early in the third. It should cover such *materia medica* as may seem essential; prescription writing, which should be practiced at every opportunity, but, above all, a thorough study of the pharmacology of the more important drugs, with briefer reference to those of lesser importance and the ignoring of those which should be discarded entirely. Such mention of therapeutics may be made as will serve to assist the student in the memorizing of his pharmacology and lend greater interest to the subject, and, in addition, give him a foundation for the courses in practical therapeutics which will be given him later.

DISCUSSION

DR. A. N. RICHARDS, Philadelphia: The spirit is the thing on which we should concentrate, and the letter consequently will take care of itself. Laboratory work and laboratory methods represent the nucleus about which the course in pharmacology must center. By laboratory work I mean not only that which the student does himself, that is, the beginning, but that which he is shown by an expert instructor of experiments which he is unable to do, which experimental work is the body of knowledge which represents science. The student must be brought to know what people have been thinking about whenever they advise experiments; and to interpret the results of the experiments, he must learn something of the value of evidence and the capacity to interpret evidence. Then he will be in a position to protect himself against embarrassment and against the half digested views of others with whom he may be confronted later on. If we can impart spirit to the student, make him see that the subject is alive, that it is a fallible thing, that it is full of holes and lots of opportunities for differences of opinion, and that the subject is intrinsically difficult, we shall have accomplished half of our task.

DR. JOHN W. SCANE, Montreal: If a student in pharmacology is given a synopsis of the things in his hands, with clear directions that he is to perform certain experiments, and is left alone to work them out in his own way, giving him no spoon feeding, no actual assistance in the performance of these experiments, and then checking the work up at the end of the laboratory period on that subject, he will do much better work. We have pursued that method at McGill in the last few years with more satisfactory results than formerly.

DR. WORTH HALE, Boston: One has to adapt the course to meet local conditions. We teach very little *materia medica* and pharmacy. We attempt to give the student a great many chemical relations of drugs in the laboratory, and devote about an equal amount of time to pharmacodynamics. The more I teach, the more I am impressed that a student can frequently get facts and historical knowledge more easily from reference textbooks and original papers than he can from laboratory experiments themselves.

DR. HUGH MCGUIGAN, Chicago: One of the greatest handicaps I find in the students that come to us is that eight out of ten know very little or nothing about chemistry. If pharmacology is indicated, it is applied organic chemistry, and the men do not know it.

DR. ALEXANDER MACALISTER, Trenton, N. J.: As a member of the state board of examiners, in conducting examinations in *materia medica* and therapeutics I find that applicants for licensure are very deficient in their knowledge of dosages and in prescription writing. At our last examination, out of twenty-six applicants, there were only two who could write prescriptions properly. I think this is largely due to the fact that these branches are taught imperfectly in the majority of medical colleges.

Pathology, Bacteriology and Parasitology

Papers were read by Dr. James Ewing, New York, on "Pathology," and by Dr. A. I. Kendall, Chicago, on "Bacteriology and Parasitology."

DISCUSSION

DR. LOUIS B. WILSON, Rochester, Minn.: I cannot wholly agree with Dr. Ewing regarding the impossibility of teaching men necropsy technic in the undergraduate course, but I do agree as to the undesirability of teaching men how to perform operations for the removal of brain tumors. It is not impossible to teach a man quickly and reasonably a good necropsy technic, and unless we teach them they will never do it.

DR. J. P. JOBLING, New York: Pathology is probably the first subject the medical student takes up, in which he applies to a large degree the work he has already gone over. To a certain extent that includes anatomy, bacteriology, physiology, biologic chemistry, etc. Pathology should be taught to as large a degree as possible by actual observation, by experimental work, and by actual necropsy work.

DR. OSKAR KLOTZ, Pittsburgh: We are realizing more and more that pathology is only a special department dealing with morbid anatomy, but more and more we must realize the human side of the subject. It has been stated several times at this meeting that pathology forms more or less of a link between the fundamental departments and clinics. It has all the attributes of the fundamental departments in their ideals. It has also another attribute of its own, and that is of making it eminently human in its application to disease. That is much more difficult than to bring in some of the other fundamental departments, such as anatomy and chemistry, but pathology is one of the subjects concerning which the student realizes, for the first time, that he is approaching his ideals in medicine.

DR. ALEXANDER C. ABBOTT, Philadelphia: The burden of the song throughout this conference has been that there is a distinct and conspicuous line of demarcation between the fundamental sciences and the practical branches of medical teaching. Let us teach our sciences in the first two years, but let us develop in some way, either at the end of the second year or in the third year, a first class, gilt edge clinical laboratory, in which we shall have coordinated all of these more or less abstract sciences, a laboratory so equipped

that these sciences can be brought to bear directly on the cases seen in the dispensary and hospital.

DR. H. GIDEON WELLS, Chicago: I wish to emphasize what Dr. Wilson said about the desirability of teaching pathologic technic with laboratory animals. We can do that easily enough, but how few laboratories do it? You can give a man a good fundamental grounding in technic by using selected material.

Tuberculosis Infection of Guinea-Pigs by Inhalation.—Rogers reports further experiments on the production of pulmonary tuberculosis in guinea-pigs by the inhalation of tuberculosis material. In all the experiments the guinea-pigs were wrapped so that only their nostrils were exposed to the spraying. All animals giving a single spraying of five minutes with a suspension of tuberculosis sputum developed pulmonary tuberculosis. Particles of tuberculosis sputum containing tubercle bacilli placed on the normal nasal mucous membrane brought about tuberculosis changes in the cervical lymphatic glands with involvement of the lungs, liver and spleen later.

Pulmonary Syphilis.—Funk believes that late syphilis of the lung occurs clinically more often than is generally taught. Diagnosis is difficult and judgment may have to be suspended until syphilis has been controlled by treatment, when "apical râles" will clear with the associated bronchitis if signs are due to syphilis. The author reports in detail three cases of what he believes was pulmonary syphilis that have come under his own observation.

Operation and Recovery in Spontaneous Pneumothorax Following Artificial Pneumothorax.—A patient with acute tuberculous bronchopneumonia was treated by artificial pneumothorax. Thirty-four days after the first introduction of nitrogen gas, and following a coughing fit, spontaneous pneumothorax developed. At first partial, within twelve days the spontaneous pneumothorax had become complete, and purulent fluid developed in the chest. The patient became very septic and gravely ill and on the eighteenth day of the spontaneous pneumothorax a rib resection was done under local anesthesia. Cocke says that after surgical operation, the patient's relief was spectacular and that his fever disappeared within a day or two and has remained normal since.

Spontaneous Hemopneumothorax Following Artificial Pneumothorax.—Heise and Krause report the case of a man, aged 21, who had hemoptysis and pain in his chest. These symptoms were so indefinite that diagnosis at first was only tentative. He did well for several months but then his condition became less favorable. After six months he was continually febrile and was having more hemoptyses. Meanwhile, his signs indicated a slight stationary process, while the roentgen-ray showed markedly progressing involvement. The fifty-sixth examination was positive for the first time. By this time the patient was gravely ill. Artificial pneumothorax was performed. The next day, after raising himself in bed, the patient suddenly experienced a sharp stabbing pain in his left side. The patient went into collapse and died fourteen hours after the rupture of his lung. At necropsy, it was found that the pneumothorax needle had not injured the

patient's lung. On the anterior surface near the caudal tip was a tear of the pleura over a small cavity and close to a short and very thick adhesion. The entire left lung was involved with a caseating process that was cavitating at numerous places. The left thoracic cavity contained about 2 liters of clotted blood.

- Tabes Dorsalis with Gastric Manifestations. A. H. Gordon.—p. 275.

Plasmoma of Nasopharynx.—Rogers reports a case in which posterior rhinoscopy revealed an uneven granular looking hemorrhagic mass, completely filling the nasopharynx and seeming to spring from its vault. The surface of the tumor showed areas of fresh and old bleeding. Digital palpation through the mouth suggested a movable and rather firm growth, any manipulation of which resulted in a persistent but not alarming hemorrhage. At this time Rogers considered the case one of nasopharyngeal fibroma. A general examination showed various systems normal. The growth was removed whole. Sections showed that it consisted essentially of plasma-like cells. A diagnosis of plasmoma was made. The tumor took origin from the inferior border of the cushion of the eustachian tube and the neighboring surface of the soft palate. A search through the literature and textbooks has failed to discover a similar case. The pathologic files of the Royal Victoria Hospital during the past five years record only two cases of plasmoma, one the subject of this paper and another which arose from the medulla of the bone.

Treatment of Obstructive Dysmenorrhea.—To overcome the objections and retain the beneficial effects of a glass cervical stem, Frederick constructed a thick hollow glass tube, 2 inches long, one-half inch in diameter, with the upper end smoothly rounded in the flame to the lower end of which a round flat vulcanite boss is firmly fastened. In the side of this vulcanite two small holes are drilled large enough to pass a needle and silk suture. The advantages of this instrument are said to be: (1) full dilatation; (2) free exit for discharges; (3) a means for suturing it firmly with silk so that it may be retained firmly as long as desired; (4) protection against rectovaginal wall perforation. The stem has been found satisfactory in the treatment of obstructive dysmenorrhea in selected cases.

Retroperitoneal Congenital Cyst Probably Arising from Wolffian Body.—A baby girl, aged 2 years, sustained an injury to the right kidney as evidenced by blood in the urine and reactionary temperature. The injury caused a congenital retroperitoneal cyst on the same side to undergo rapid increase in size. The anatomic situation and the general characters of this cyst were such as in Elder's opinion to warrant a diagnosis of cyst of the wolffian body.

Chronic Benzol Poisoning.—Two cases of purpura hemorrhagica in rubber spreaders are reported by Legge, and he claims that they are the first cases of chronic benzol poisoning known to have occurred in England. The history of these cases was practically identical, commencing with malaise and anemia, which was followed by subcutaneous and submucous hemorrhages, and both men were eventually admitted to hospital suffering from bleeding from the nose, gums and bowels. The blood count in the first case was as follows: red blood cells, 2,800,000 per cubic millimeter; leukocytes, 2,000 per cubic millimeter; hemoglobin, 35 per cent.; color index, 0.6. The chief characteristic of the post-mortem examination in both cases was numerous submucous hemorrhages throughout the intestinal tract and under the endothelium of the heart. In the second case, where a more detailed examination was available, characteristic changes were observed in the bone marrow of the long bones. The conditions observed in life and after death were those seen in cases of aplastic anemia and are identical with those which have been noted in twelve cases (all fatal) arising from poisoning by T. N. T.

*Australian Epidemic of Acute Encephalomyelitis. J. B. Cleland and A. W. Campbell, Sydney.—p. 137.
*Possible Significance of Babinski and Other Pathologic Reflexes. E. D. Friedman, New York.—p. 146.

Acute Encephalomyelitis.—The authors believe that the paucity of cases in the Australian epidemic is chiefly due to the fact that many individuals in the community react to the presence of the virus and its toxins in the nervous system to such a slight degree that no interference with physiologic function results, hence there are no manifestations of illness. In other individuals the reaction is a degree heavier, and these are the abortive cases; in a few individuals the reaction is great and interference with function is pronounced.

Significance of Babinski Phenomenon.—It is suggested by Friedman that it is possible that all pathologic reflexes are an expression of an atavism. A lesion of the corticospinal system causes man to revert to the stage of the tree climbing monkey in whom there seems to be a dissociation between the great toe and the little toes. The presence of a positive Babinski in epilepsy would be explained by the injury to the corticospinal system and that the reflexogenic zone for elucidating these pathologic reflexes could most readily be explained on the assumption of adaptation to function.

*Case of Blastomycosis Involving Prostate and Seminal Vesicles; Recovery. F. J. Parmenter and B. T. Simpson, Buffalo.—p. 449.
Nephritis in Fifty-Six Soldiers. H. Gray, Boston.—p. 459.

Massive Degeneration in Tuberculosis of Kidney and Its Role in Clinical Cure.—Randall pleads for the putting forth of greater effort to establish the possibility of cure by anatomic healing. He reports a case in which renal tuberculosis was not only primary, but was unilateral, and it was likewise completely destructive of the organ. Spontaneous "autonephrectomy" succeeded; the infectious character was ultimately conquered, and the patient succumbed to a disease in no way related to his renal disease—pernicious anemia. The diagnosis was made at the time of the necropsy.

Migrating Bladder Stone.—On making a rectal examination of a man, aged 50, Barringer found just within the anal sphincter a stone nearly as large as a hen's egg. The stone was black, rough and shining like coal. Twelve years before the patient had a perineal section and perineal drainage. Ten years ago he entered a hospital because of partial retention of urine, dribbling and abscess formation in the perineum. He was told that he had a growth in the rectum because of marked constipation and straining at stool. Another perineal section was performed. Ever since this last operation he noted, at intervals, the escape of urine from his rectum and fecal matter from his urethra. For the past six months this has been constant, with great urinary tenesmus and very often fecal and urinary incontinence. He has had the sensation of some obstruction and dull pain in his rectum, and has noted that his stools were ribbon-like. A year ago he again went to a hospital because of an abscess in the perineum. This was opened. The patient has never had a rectal injury, and never had introduced any foreign body into his urethra. He had an attack of gonorrhea at the age of 21. The stone had as a nucleus a piece of the shaft of a long bone. This center nucleus was surrounded by lamellae of phosphatic crystals in which no fecal matter was found except in the way of slight staining. This, in the author's opinion, clearly indicates that the stone arose in the bladder.

Control of Hemorrhage After Suprapubic Prostatectomy.—After enucleation of the prostate, Barringer inserts a strip of 2-inch gauze, several yards in length, through the open bladder into the bed from which the prostate has been removed. The gauze is packed into the prostate bed with the index finger of the right hand, or with a plain thumb forceps, against the counter pressure of two fingers of the left hand which have been previously inserted into the rectum to aid in enucleating the prostate. Enough gauze is used to overfill the prostate cavity. With the hemorrhage controlled, a simple sponge stick is passed into the bladder and the gauze ball grasped by this. The bladder is sutured to the rectus fascia and the hole in the bladder sewed up,

simply allowing space for the gauze and sponge stick. No tubes are put into the bladder but the urine finds exit alongside the sponge stick and gauze. The dressings are changed as often as they are saturated. If the bleeding begins again, pressure on the sponge stick controls it.

Blastomycosis Involving Prostate and Seminal Vesicles.—The patient whose case is recorded by Parmenter and Simpson is said to be one of the few to recover from extensive systemic blastomycosis. Only in the epididymis is there any evidence of the disease after four years, during which time the lungs, skin, muscles of the leg, prostate and seminal vesicles have been involved.

Chronic Anilin Poisoning.—A case of chronic anilin poisoning, manifesting all of the typical symptoms, namely, vertigo, gastritis, diplopia, asthenia and an exfoliative dermatitis, is reported by Thompson. The cause of the poisoning was a French hair dye called "goute à goutte." The type of anilin was paraphenophendiamin, 2 per cent., hydrogen peroxid, 75 per cent., and alcohol, 23 per cent. Thompson points out that the menace of anilin hair dyes has not yet sufficiently been emphasized to be appreciated generally by the medical profession. The fact that personal susceptibility varies as much as in the case of poisoning, for example, by Rhus toxicodendron, only makes it more difficult always to recognize such cases. It is well to be suspicious of artificial Titian red hair and all the darker shades up to jet black.

 Cancer Problem. E. H. King, Portland, Me.—p. 444.

Etiology of Thrombo-Angiitis Obliterans.—Meyer asserts that the characteristics of the patients who are particularly prone to develop thrombo-angiitis obliterans seem to indicate a hereditarily weak sympathetic nervous system. Hence, the functioning of the eliminating glands (kidneys, etc.) innervated by that nervous system, is probably subnormal. When the system of such a patient is kept incessantly flooded with tobacco smoke poisons over long periods of time, the elimination of the poisons by these glands is liable to fall behind, and the system will gradually become saturated with the poisons. This is the starting point of the trouble. Vicious circles of various types, a general upset of physiologic balances in the blood, tissue asphyxia, etc., are induced, and cause, secondarily, blood vessel lesions which in time lead to the onset of the symptom complex known as "intermittent limping" and, under certain conditions, to the culminating development of the disease, "gangrene." The only real cure for the disease is prophylaxis. People so constituted as these Hebrews are should not smoke. They should be warned in good season—at home, in school, from the pulpit—of the deleterious effects and serious consequences to them of the excessive use of cigarettes.

Chemical Blood Findings in Thrombo-Angiitis Obliterans.—The results of investigation of the sugar tolerance test in thirty-six verified cases of thrombo-angiitis obliterans revealed the following: 1. The blood sugar concentration at the zero hour varies between 90 and 210 mg., with an average of 115 mg. per hundred cubic centimeters, the urine showing no sugar at the zero hour. 2. The blood sugar at the end of the forty-five minute period varied between 106 and 344 mg.,

with an average of 179 mg., and 36 per cent. of the patients showed sugar in the urine at the forty-five minute period, of which 23 per cent. had a lower blood concentration than 150 mg. Six patients had a blood sugar concentration of 180 mg. or higher without showing sugar in the urine, and 69 per cent. showed a concentration of 150 mg. or more. 3. The blood sugar at the end of the two-hour period varied between 96 and 288 mg. with an average of 146 mg.; 33 per cent. showed sugar. 4. In three cases, or 8 per cent. of all the cases, Type I reaction was obtained; 92 per cent. of the cases gave Type II reaction. In none of the cases did Type III reaction result. In contrast, the series of 300 other cases gave 36 per cent. Type I, 55 per cent. Type II, and 9 per cent. Type III.

Pathology of Thrombo-Angiitis Obliterans.—The lesions in thrombo-angiitis obliterans as noted by Buerger are, in chronologic order: (1) an acute inflammatory lesion with occlusive thrombosis, the formation of miliary giant cell foci; (2) the stage of organization or healing, with the disappearance of the miliary giant cell foci, the organization and canalization of the clot, the disappearance of the inflammatory products; (3) the development of fibrotic tissue in the adventitia that binds together the artery, vein and nerves.

New Method of Phagocytosis Test with Blood Plasma.—This method is described in such detail that the original article should be consulted. The basis of the method is the observation that the citrated or oxalated blood plasma of persons infected by a certain species of pathogenic micro-organism has been found to have a remarkably augmented phagocytal power against that particular species of micro-organism. The acceleration of phagocytosis is considered to be one of the immunologic reactions, by means of which an early diagnosis of tuberculosis, typhoid fever and dysentery may be established. The method is far more simple than Wright's opsonin test. It can easily be applied for clinical purposes as well as for immunologic investigation.

Blood Pressure in Aortic Aneurysm.—The only symptom complained of by Crance's patient was "slight pain in the chest with an occasional shortness of breath," but the pathologic findings were quite numerous. There was a decided difference in the pressure in both arms, an important sign which points toward aneurysm. Hence, Crance believes, the blood pressure should be taken bilaterally in all cases presenting cardiovascular symptoms. He also is of the opinion that chancres occur within the urethra, associated with gonorrhea, more often than has been realized.

Colon Bacillus in Vagina as a Cause of Leukorrhea and Sterility.—Barbash uses autogenous vaccines in all cases of leukorrhea with very gratifying results. He also uses local treatments consisting of tampons impregnated with a preparation containing ichthyol, iodine and phenol. The vaccines invariably contained the colon bacillus together with one of the staphylococci. These cause at times a profuse leukorrhea with highly acid reaction, which in turn may cause ulceration in the vagina. The colon bacillus by reason of its acid producing ability renders the patient sterile.

Roentgen-Ray Studies of Functional Alterations of Diaphragm.—Greater study of the diaphragm movements is urged by Pancoast. Interference with the action of the diaphragm is readily detected by the roentgenoscope and this may be an important means of determining the structure effected and the pathologic conditions responsible for the functional disturbances of the muscle. The study of the diaphragm is, therefore, an important means of diagnosis, and in a few instances, the sole source of knowledge whereby the condition present can be determined. These conditions are detailed by Pancoast.

Somatic Symptoms in Nervous and Mental Diseases.—A condition met with infrequently to which Dercum calls attention is one in which primary nervous disease and primary visceral disease coexist in the same patient; for example,

brain tumor and hysteria, pelvic disease and hysteria. A case in point is cited. The early history suggested an actual lesion of the esophagus due to some trauma in the act of swallowing, perhaps from a bolus of hard or mechanically irritating mass of food, and the first esophagoscopy seemed to confirm this. Later, it seemed as though the symptoms had their origin in a spasm of the esophagus; later still the symptoms suggested hysteria, particularly as they disappeared for a time under suggestion. However, convulsive seizures which were neither reconcilable with those of hysteria or of a true epilepsy, remained unexplained. It was only the later appearing mental features which led to a correct appreciation of the case. Evidently the case was one of dementia praecox in an early stage, the symptoms of which at the time the patient first presented himself were just beginning to reveal themselves. His early conduct and general demeanor in the wards became increasingly explicable as he continued under observation. It would appear further that the convulsions which the patient described and which were difficult to classify, are to be regarded as among the epileptiform attacks—the motor crises—every now and then met with in cases of dementia praecox, especially in the developmental period. Finally, the case teaches a valuable lesson as to the interpretation of local or visceral symptoms, when the latter have no or little physical foundation, and when, still further hysteria offers an inadequate and unsatisfactory explanation.

Tumors of Uterus.—Evans makes a very detailed analytical report of the study of seventy-two cases in a series of 4,000 operations for uterine fibromyoma.

Treatment of Tuberculous Osteoarthritis by Bone Grafts.—LaValle uses grafts which extend from the diaphysis to the epiphysis without touching the articular cavity or coming in contact with the tuberculous tissue.

Origin of Tumors of Ovary.—Goodall's work is based on sections, both serial and nonserial, from ovaries of 127 females of all ages, from a few hours to 80 years, as well as on serial sections of five human embryos. The comparative study covers, roughly, 15,000 sections, mostly serial, from the cow, pig, sheep, cat, mouse, rabbit, guinea-pig and the dog, and from the embryos of the cow, dog, pig and cat. He takes up the histology of the ovary, the significance and origin of its various structures, its analogy to the testis and the origin of various tumors of the ovary.

Osteomyelitis and Periosteitis Complicating Epidemic Influenza.—Behrend reports five cases in one of which the radius was removed. He also reviews the literature of excision of the radius.

Frequency and Significance of Omphalitis.—On microscopic examination of the cord in 2,200 consecutive cases in which the infant weighed more than 1,800 gm., forty-three specimens showed leukocytic infiltration of the vessel walls and the adjacent connective tissue. The lesion is not pathognomonic of syphilis, for (a) it was present in forty cases where there was no evidence of syphilis, and (b) it was absent in twenty-nine cases of undoubted syphilis. The lesions arises by the extension of bacterial infection from the placenta. Bacteria are frequently demonstrable in sections of the cord. The lesion is commonly associated with prolonged labor after premature rupture of the membranes. The frequency of these infections and the resulting infant mortality, Creadick says, may be reduced by the use of rectal in plate of vaginal examinations.

Carrel-Dakin Method in Acute Appendicitis.—The anti-septic treatment of cases of acute appendicitis requiring drainage was undertaken by Rulison in February, 1918, as a routine. Eighteen patients have been treated by him. During the procedure of appendicectomy and drainage of a peritoneal abscess an extensive contamination of the operative wound necessarily occurs. In the cases reviewed by Rulison, the average period of suppuration was 15.4 days, during which time the majority of the wounds discharged foul pus and sloughs. The average duration of hospital stay was twenty-eight days. Among the frequent complications, fecal fistula developed in 7.5 per cent. of the cases. There was a 9.1 per cent. mortality. Whether the course of these cases may be improved in any of these essential particulars by the use of antiseptics is dependent on their safe application and a determination of their efficiency in this type of infection. Severe pain reactions and shock attend the introduction of surgical solution of chlorinated soda into the free peritoneal cavity. The use of this antiseptic must, therefore, be restricted to the treatment of the drainage tracts after the period of walling-off has occurred. The injections are, therefore, not intraperitoneal but intra-abdominal. The satisfactory establishment of a water-tight drainage tract seems to depend as to its rapidity of formation on the type of infection. Great caution as to time and manner of introducing the fluid is necessitated. Accidents involving the integrity of intra-abdominal drainage tracts, with escape of the fluid into the free peritoneal cavity, are attended by grave danger, especially if infection be present. Less slough and less foul discharge were noted in the cases treated by this method. The average time when all treatment was stopped and dry dressings applied was 13.8 days. There was no gross suppuration in seven cases, and profuse suppuration in five cases. The discharge was odorless throughout in two cases. The average duration of odoriferous discharge in fifteen cases was only six days, and in a number of cases the odor was slight. There were no cases of disruption of the wound, and only one case in which real wound infection occurred. The details of the procedure are given and the results obtained are analyzed.

 *Ankylosis of Mandible and Its Operative Treatment. G. Chubb.—p. 257.

Atony and Prolapse of Large Intestine.—The symptomatology of this condition, Smith says, is quite definite. In the majority of cases there is a history of a distinct starting point. Quite often it has been a continued and severe attack of abdominal pain, usually right iliac or lumbar, with confinement to bed for from two to three weeks. After subsidence the pain continues, more marked at intervals, which tend to become shorter. When the pain is right iliac, the symptoms strongly suggest a subacute appendicular attack, without pyrexia, and doubtless this has actually been present in many cases. Sometimes the pain is right lumbar, in the subhepatic area. In such cases one suspects kinking at the hepatic flexure. Much rarer is left iliac pain. In the cecum a succussion splash is usual in the right semilunar line, above and outside McBurney's point, but below the level of the umbilicus. This may also be found on the left side in the pelvic colon cases. Constipation, though frequent, is not constant. Dull, aching abdominal pain and feeling of weight is very constant, either in the lower abdomen, more marked to the right, or in the epigastrium. Its occurrence may or may not be associated with the taking of food, but it is often associated with the erect posture, and is then relieved by lying down, and often by manual support of the abdominal wall. Gastric or duodenal trouble, sometimes with frequent vomiting, sometimes with epigastric pain after food is noted. Abdominal crises, such as accompany floating kidney, are associated with enteroptosis. Very marked pulsation of the epigastric aorta, sometimes visible pulsation, is frequent. After some experience, paying attention to these points, Smith states a diagnosis can generally be made. In the great majority of these cases, especially in their early stages, medical treatment alone is needed, and very frequently, if carried out carefully and continuously, it effects either a cure or such amelioration as to render life comfortable and useful.

Effects of Deficient Dietsaries.—Dietsaries which are deficient in vitamins and in protein, and at the same time excessively rich in starch or in fat, or in both, are, in McCarrison's opinion, potent sources of disease, and especially of gastro-intestinal disease. An excess of fat, in association with deficiency of "B-vitamin" and protein and super-

abundance of starch, is peculiarly harmful to the organism. Certain dietetic deficiencies greatly favor the invasion of the blood and tissues by bacteria; especially is this the case when deficiency of vitamins and protein is associated with an excessive intake of starch. Since life cannot be sustained in the monkey for much longer than 100 days on a dietary almost wholly devoid of "B-vitamin," it would appear that complete absence of this vitamin from the food is of less practical importance from the point of view of the production of disease in human beings than its subminimal supply. Complete deprivation of "B-vitamin," especially if there be also imperfect balance in other essential requisites of the food, will lead to rapid dissolution and death; subminimal supply of this vitamin will lead, in like circumstances, to slow dissolution and disease. McCarrison suggests that his findings may afford some explanation of the genesis of that great mass of ill defined gastro-intestinal disorders and vague ill health which forms so high a proportion of human ailments at the present day.

Some Unusual Forms of Dysentery.—As proof that other conditions, many of them very common, may produce an almost similar clinical picture to real dysentery, Low cites the following cases: syphilitic ulceration of the rectum; large fungating malignant growth in the rectum; advanced tuberculosis of the lungs, with extensive tuberculous ulceration in the small and large bowel; schistosomiasis infection only; *paragonimus* dysentery; *heterophyses* dysentery; ankylostomiasis; balantidial dysentery, pseudodysenteries, such as foreign bodies impacted in the rectum above the anus.

Ankylosis of Mandible and Its Operative Treatment.—Chubb reports five cases in which removal of the coronoid process overcame the ankylosis. No tissue flap transplantation was done.

*Mental Cases of Endocrine Considerations. G. P. U. Prior.—p. 23.
Treatment of General Paralysis. G. H. M. Krohn.—p. 46.

Mental Cases of Endocrine Considerations.—In a series of forty-six postmortem examinations, in which the glands had been taken for examination, twenty-five persons had a definite thymus gland. Among these forty-six cases were thirty-two epileptics; twenty-two of these latter had the thymus present. The largest glands were found among the epileptics. Eight epileptics died a sudden death. All had enlarged thymuses. The suprarenals showed degenerative changes in fifteen cases. In four patients there was a deficiency in the interstitial cells of the testes. The pituitary showed no constant change in twenty cases; it was either normal or of slightly increased activity. The thyroids were mostly of two types, seven being taken as being quiescent and twelve as of overactivity. The pineal gland of two examined showed degenerative changes. The liver from nineteen patients was examined. Thirteen showed signs of fatty degeneration or fatty infiltration. The pancreas was reported on from fourteen patients. In nine, the islets of Langerhans were few in number and showed degenerative changes. The spleen from eleven patients was examined. From one case it was reported normal, in one there were small hemorrhages, in two waxy degeneration; six showed fibrotic changes. In twelve female cases an enlarged thymus was found in seven. Of the ovaries in eight cases, the fibrous tissue was much increased and the organs were shrunken and atrophic. In three instances, small Graafian follicles were seen. Most worthy of note in these results is the large percentage of cases in which the thymus is found to persist, and the great number of times in which there is found degenerative changes in the suprarenal cortex. That the liver, spleen and pancreas are seldom reported to be normal is suggestive, but the number of times these organs have been examined is not sufficient to say that changes are constant. The fibrotic and atrophied ovary appear to be present almost invariably, and the fact that the menstrual function is most irregular in epileptics may depend on this.

A corresponding change is not found to the same persistency in the male sex gland.

Case of Hirschsprung's Disease (Megacolon) Causing Acute Obstruction. I. Tewfik.—p. 435.

Tumors Complicating Pregnancy, Labor and Puerperium.—Of the cases recorded by Spencer, three were terminated by death. The first death resulted from intestinal obstruction, due to nipping of the ileum between two subperitoneal fibroids—a very rare accident, of which Spencer has not been able to find another example. The other two deaths suggest the necessity of bacteriologic examination of the tumor before resorting to conservative abdominal operations. In one case there was present a foul discharge, after a miscarriage which had occurred six days previously at the second month. Spencer enucleated a sessile submucous myoma and removed a mass of putrid decidua in 1898. Subsequently the woman gave birth to two children. She remained in good health till 1917, when she began to lose considerably, and the abdomen increased in size. She became cachectic. She had a large, fixed, irregular, uterine tumor, nearly filling the abdomen. She had also pleural effusion and hemoptysis and other signs of growth in the lungs. From the cachectic condition, the hemorrhages and foul discharge, it appeared probable that the growth was a uterine sarcoma. The woman died nearly twenty years after the enucleation of the fibroid.

Abscess of Liver Among British Eastern Troops.—The points of importance to which Candler directs attention are that often there is no history of diarrhea or dysentery in these cases; often no amebas are found in the feces, and even in fatal cases little or no ulceration of the bowel is found postmortem. Fairly low temperature, pulse rate, and leukocytosis are not always contraindicated of the presence and quantity of pus. The liver may not be enlarged downward, or only slightly so, because of necrosis around the abscess occurring rather than the liver enlarging or being pushed downward. If the puncture fails to find pus in a case diagnosed clinically, an epigastric incision should be made in an attempt to get a scientific early diagnosis and treatment. Drainage should be free, followed by daily sterile dressing and a course of emetin hypodermically. The drainage tubes should be removed as early as possible to prevent secondary infection and sinus formation. Inflamed lung is liable to disguise inflamed liver below and beneath it.

Intravenous Injection of Hydrogen Peroxid in Influenzal Pneumonia.—There occurred in Bushra in June and July, 1919, a severe epidemic of influenza, most marked among Indian troops, and accompanied in many cases by an exceedingly toxicemic and fatal bronchopneumonia. In one large Indian hospital in which the influenza cases were segregated in special huts, the death rate was over 80 per cent. in the pneumonia cases with toxic symptoms. So useless were the usual remedies tried in this latter class of case, that Oliver and Murphy felt justified in giving a trial to the intravenous injection of hydrogen peroxid. The first case was one of bronchopneumonia of influenzal origin and intensely toxicemic. The patient had been delirious for two days previously, and was selected as being the worst case in the ward and to all appearances moribund. Two ounces of a ten volume solution of hydrogen peroxid were diluted with 8 ounces of physiologic sodium chlorid solution, and the solution made slightly alkaline with 5 minims of liquor ammoniae. This produced a faintly effervescent solution. The median cephalic vein was exposed by open dissection, and the solution infused through a glass cannula attached to a Rogers apparatus.

The solution was infused very slowly, a complete stop being made for half a minute in every four. Small bubbles were allowed to enter the vein unchecked, but if a large accumulation of oxygen appeared in the cannula, the transfusion was checked for about one minute until it had gradually entered the vein. The whole transfusion lasted for fifteen minutes. The patient showed no signs of discomfort until toward the end of the operation when he became slightly restless. This, however, passed off in a few minutes, and there were no other untoward symptoms, except a moderate rigor which occurred two hours later. After the rigor, the temperature which had been 101.8 F. fell to normal and remained so for thirty-six hours, when it again rose to 101 F. The latter rise was not accompanied by toxic symptoms and the temperature gradually fell to normal in the course of the next ten days. The change in the mental condition was remarkable. The patient, who previously had had to be tied in bed owing to delirium, was sitting up within six hours of the injection and asking for food; he slept well the next night and from that time improved in every way, eventually being invalided to India as a walking case three weeks later. Encouraged by the apparent success in this case, the authors tried the method in twenty-four other cases of influenza pneumonia, selecting always those patients whose condition was apparently hopeless. Of the total of twenty-five cases, thirteen patients recovered and twelve died, a mortality of 48 per cent. Of the twelve who died, nine showed no visible effect for either good or ill. In three there was a temporary improvement. One patient died within five hours of the infusion, during a rigor. One patient had four injections at intervals of from three to five days without any sign of gas embolism, nor were there any signs of such embolism post-mortem.

*Hydatid Infestation of Bone: Multilocular Hydatid Disease and Ordinary Hydatid Cysts. C. W. Corlette.—p. 73.
Case of Xanthoma Diabeticorum. R. E. Harrold.—p. 84.

Multilocular Hydatid Disease of Bone.—Following several traumatic injuries of the right thigh sustained many years ago, Corlette's patient noticed the appearance of a small swelling in the groin, and a larger swelling below the inguinal ligament. The roentgen-ray appearance suggested a new growth. At operation this mass was found to be mixed with smaller and apparently granular material. The main cavity intercommunicated with other larger and smaller loculi around the upper part of the femur, and these again with other cavities passing up behind the iliac bone and through erosion holes and also via the obturator foramen into the pelvis and thence upward. There was a very large cavity extending up over the dorsum ilii. There was also an enormous ramifying cavity reaching from within the pelvis up along the general course of the psoas as high as the liver, but not invading the liver and not invading the kidney. The cavity was medial in relation to the kidney, and partially covered it. As for the bone, the right side of the pelvis was eroded everywhere, and its skeletal structure was reduced to a fretwork, or network, of thin bone. The acetabular cup had vanished, and with it had vanished the head of the femur. Through the perforation extended a large branch connecting the upper cavity with a cavity in the femur. The neck of the femur was tunneled by this, so that only the cortical part survived. In addition to the system of intercommunicating cavities on the right side, other separately encapsulated accumulations of the same material were discovered at the postmortem examination. One was a very large sac lying in the soft parts of the thigh, mainly posterior. It reached from the level of the upper end of the bone above nearly to the popliteal space below. Another was a sac between the spleen and the diaphragm, the top of the spleen forming its floor and the under surface of the

diaphragm forming its roof. A multilocular hydatid of the right lung was also present.

*Etiology of Pellagra. A. Viswalingam.—p. 46.

Etiology of Pellagra.—From careful observation, Viswalingam is lead to conclude that faulty diet, in itself, cannot cause "pellagra" and that there is a superadded infection. If diet should be the sole factor, then the effected individual should improve and there should be no recurrence when he is removed to a hospital and placed on liberal diet. But this is not so; therefore, apart from diet, sunlight, etc., there must be some other factor, probably a toxin. The habits of the people, the poor dietary, the extremely insanitary surroundings in which they live, the initial gastro-intestinal troubles, the condition of chronic fibrosis seen in the organs drained by the portal circulation, and many other minor factors, Viswalingam says, favor the view that the infection must be through the alimentary canal. Whether the infecting agent is an organism which enters the gastro-intestinal system and produces a toxin which is absorbed into the system and produces the varied symptomatology, or whether owing to a deficiency in the vitamins, some deleterious products are created in the intestines and give rise to an intoxication of the system, it is difficult to say at present. The seasonal recurrences of symptoms in patients removed from their surroundings and placed in a hospital with adequate diet for considerable periods of time, would point to the presence of an endotoxin resulting from the evolution of some organism or more probably the establishment of a vicious circle brought about by profound metabolic changes. Among predisposing causes are mentioned dysentery, ankylostomiasis, malaria and scurvy. Evidences of one or the other of those were present in at least 60 per cent. of the cases seen by the author.

Bulletin de l'Académie de Médecine, Paris

Feb. 3, 1920, 83, No. 5

*Lethargic Encephalitis. P. Marie and Mestrezat.—p. 103; Idem. C. Achard.—p. 106; Idem; P. Remlinger.—p. 112.
*Influenza and Pneumonic Plague. C. Broquet.—p. 116.
The Fight Against Tuberculosis. Coubard.—p. 119.
*Operative Treatment of Empyema. P. Peugniez.—p. 122.

Lethargic Encephalitis.—Marie and Mestrezat report that in their six cases the cerebrospinal fluid was almost completely normal. The lymphocytes numbered only from 8 to 26. Netter, on the other hand, noted considerable lymphocytosis on repeated examination. In one of his three cases, the number was 14, 16, 84 and 30 in nineteen days; in another 56, 118, 16 and 9, and in a third, pronounced lymphocytosis at first was followed by 60 and 24 in five days. Achard comments on the wide differences in the clinical pictures now encountered. One man had been having fever for ten days, with headache, a little delirium at night, but no paralysis, somnolency or other symptom. The twelfth day the characteristic somnolency of lethargic encephalitis developed. He says, "La maladie est polymorphe et acyclique." The mental, motor and general phenomena, however, in their various forms and combinations cannot be fitted into any of the frames of classic pathology. Others spoke of the appearance of the disease in Africa and Japan. A resolution was adopted appealing to physicians to report to the Académie the cases of the disease as they encounter them, specifying the address of the patients and the probable date of the onset, in order to centralize the data.

Influenza and Pneumonic Plague.—Broquet was sent to Manchuria in 1911 to study the epidemic of plague, and he urges the necessity for applying in prophylaxis of influenza the whole series of measures found effectual in arresting the spread of plague. They should include protection of the face, disinfection, aeration, forbidding of public gatherings, quarantine in the ports, vaccination of arrivals, and serotherapy against the known germs (Pfeiffer, pneumococcus and streptococcus).

Operative Treatment of Empyema.—In Peugniez' case the chronic empyema had followed influenza, and it was treated by Delorme's decortication, removing the thick fibrous shell over the lung which had shrunk back against the spine. The lung expanded at once, and the empyema was cured. But radical paralysis of the left brachial plexus followed. It gradually subsided, and not a trace was left by the second month.

- Paralysis of Abdominogenital Nerves After Influenza. L. Moreau.—p. 81.

Ocular Manifestations of Botulinus Poisoning.—Four men developed the classic symptoms of botulism after eating from a can of smoked trout, and in addition they presented extreme and persisting congestion of the papilla and retina, with amblyopia. The optic nerve and retina lesions were still evident six months after, as also considerable contraction of the visual field for white and even more for other colors, but there was no scotoma or imperfect discrimination of colors. The asthenia also persisted exceptionally long. This and the torpor were so marked at first that the men could not leave their beds for almost three weeks. De Saint-Martin suggests that these comparatively severe and long persisting ophthalmoscope findings may aid in the differential diagnosis of botulism at the time and even months later.

Meningeal Reaction with Diphtheric Paralysis.—Ducamp and Carrieu found only 5 leukocytes per cubic millimeter in the cerebrospinal fluid in the case described, although there was up to 2.4 gm. of albumin, and also 6.9 gm. sodium chlorid.

Varying Urea Content of Blood in an Epileptic.—The epileptic seizures developed for the first time after several injections of neo-arsphenamin, but they returned after suspension of the drug. They came on at night. The urea content of the blood had been between 0.25 and 0.40 per liter at other times, but a few hours before the seizure it ran up to 0.84, dropping nearly to the former figure next day. The intervals between the seizures were long, so the phenomenon could be studied well in the young woman.

Sugar Infusion in Nephritis.—Rathery and Boucheron cite literature which confirms the value of injection by the vein of a 30 per cent. solution of glucose as an excellent means for stimulating diuresis in appropriate cases. In grave toxic-infectious conditions it has often proved extremely useful, but some recent experiences warn that this measure is distinctly contraindicated in chronic nephritis with azotemia. In three cases studied in detail no diuresis followed; the output of urine decreased, and the azotemia increased, all the symptoms becoming aggravated.

Syphilitic Diabetes.—Carnot and Harvier report a case of diabetes in a woman of 53 with neurosyphilis in which necropsy showed the entire pancreas transformed into sclerogummatous tissue. The urine had been abundant and contained from 66 to 72 gm. of sugar per liter after two years of the diabetic symptoms, a few days before death from pneumonia.

Primary Typhoid Cholecystitis.—Panayotaton relates that typhoid bacilli were cultivated from the pus in the gall-

bladder. There had been no symptoms from other organs or regions, and the fever had been of the cholecystitis type, not suggesting typhoid in any way, but the rapid and complete recovery after removal of the gallbladder confirms the causal connection. The case sustains the view that infection with the typhoid bacillus may induce other clinical pictures instead of the classic typhoid fever, analogous to the extrapulmonary manifestations of the pneumococcus.

- Opening Lecture of Clinical Medicine Course. C. Achard.—p. 85.
- Clinical Parasitology of Malaria. C. Paiseau and J. Rutinel.—p. 91.

Influenza Pandemics.—Teissier was sent to Russia in 1890 to study the pandemic of influenza, and his report in 1891 sums up equally well his conclusions from the recent visitation, namely, that some particular cosmic conditions suddenly enhanced the virulence of a pathogenic germ—probably some ordinary micro-organism—and this opened the portals to secondary infections. Only individual prophylaxis is effectual, with strict isolation of *les grippés*. He adds that although the cosmic conditions may enhance the virulence to a point beyond all means of defense, yet as a rule the malignancy is in ourselves. The exceptional mortality of the pregnant confirms this.

Mishaps with Arsphenamin.—Emery and Morin report a case in which the first injection of arsphenamin caused no disturbance, but forty-eight hours after a second injection, urticaria, joint pains and fever developed, as in serum sickness. The case stands midway, they say, between the major arsphenamin anaphylaxis (nitroid crises, serous apoplexy) and the minor manifestations (fleeting eruption and benign jaundice). These experiences suggest application of the principles of anti-anaphylaxis by preliminary injection of very small amounts before the main dose. They have been applying this method in a large number of cases, and say that although it conflicts with certain theories in vogue, yet the practical results are gratifying. Their method is to begin with 0.02 gm.; 0.03; 0.04; 0.05; 0.08; and 0.10 on successive days before beginning the course proper. Sicard has recently reported injection of daily doses of 0.3 gm. of neo-arsphenamin kept up for months, and none of the patients ever exhibited the slightest tendency to serious mishaps.

- *Estimation of Chlorids in the Serum. Rodillon.—p. 85.
- The Schick Test for Susceptibility to Diphtheria. M. Nathan.—p. 86.

Serotherapy of Typhoid.—Rodet and Bonnamour applied serotherapy to 246 typhoid patients, with complicating influenza in some cases, and they state that benefit was apparent in every stage of the disease, but was most pronounced when started early. The fever and the other signs of toxic action were distinctly abated; complications were warded off, and the mortality reduced. They were unable to give baths in their service, and the serotherapy effectually took the place of hydrotherapy. They add that the antiserum is harmless and there are no contraindications. It should be given at the first suspicion of typhoid, without waiting for bacteriologic confirmation. They injected it subcutaneously; exceptionally, by the vein, and would not hesitate to inject it intraspinally in typhoid meningitis. They wait forty-eight hours after the first injection, and still longer if the fever is going down. If it keeps high, or runs up again, they give a second injection at once and repeat after forty-eight hours. The dose of 15 c.c. seems the optimum; no better results were obtained with larger doses, and less than this is ineffectual. The mortality was 4.7 per cent. in the civilian service and 5 per cent. in the military until influenza appeared. After that the figures were 12.4 and 7.6, respectively.

Chlorids in the Blood.—Rodillon expatiates on the importance of determination of the chlorids in the blood as an

index of conditions in the kidneys. He commends as far superior to all other methods the Moog technic followed by the Charpentier-Volhard technics as very reliable and rapid. Exactly 11.7 c.c. of the filtrate after treating the serum with an equal volume of a 20 per cent. aqueous solution of trichloroacetic acid, is mixed with 10 c.c. of tenth-normal solution of silver nitrate and 50 or 60 c.c. of distilled water, and 10 c.c. of a saturated solution of ammonioferric alum. Then a tenth-normal solution of ammonium sulphocyanid is added from a graduated buret, agitating constantly, until a persisting red tint appears. The chlorid content in grams per liter serum equals the number of cubic centimeters of the sulphocyanid used.

Tentative Chemotherapy in Tuberculosis. G. Salles.—p. 28.

Hematoma from Horseback Riding.—Cathelin remarks that unless one thinks of the possibility of a lesion of this kind, the differential diagnosis is difficult. The strain on the muscle occurs when vaulting on the horse. The pain gradually increases, and a large tumor develops behind the rectus abdominis. The hematoma subsides in a week or two under strict bed rest, with a compressing bandage and application of moist heat. In the eight cases described, the patients were all new recruits being trained for the cavalry.

Concussion of Cervical Spinal Cord. A. Barhé.—p. 40.

The Leukocyte Reactions.—Loeper presents the prevailing assumptions on the nature and functions of the leukocytes, and mentions a number of personal experiments. In normal rabbits, for example, after injection of epinephrin, the polynuclears show a slight increase while the mononuclears decline. In a previously vaccinated rabbit, however, a similar injection causes the polynuclears to drop while the mononuclears run up to over 15,000. This type of cell seems to share essentially in the production of antibodies, and increasing numbers presage recovery and immunity. The leukocytosis induced by the fixation abscess (from subcutaneous injection of 1 c.c. of oil of turpentine) proved very useful during the influenza epidemic. He adds that some quite remarkable instances of its efficacy here have been published.

*The Gastric Mucosa with Ulcer. E. Fricker.—p. 63.
Improved Devices for Mechanical and Hot Air Treatment. Von Neergaard.—p. 68.

Influence of Influenza on Pregnancy and Childbirth.—Beuttner and Vulliét state that 23.3 per cent. died of forty-seven pregnant or parturient women with influenza in their service. The mortality was highest in the cases in which the influenza arrested the pregnancy, abortion or premature delivery following the onset of the influenza. The younger age, and the first pregnancy, seemed to offer the greater dangers. When influenza developed postpartum, it ran a mild and uncomplicated course, probably owing to the hyperleukocytosis which is the rule in parturients. If this assumption proves to be correct, it suggests that the serum of parturients might possibly be used in treatment of influenza. The death rate among the prematurely born was 60 per cent. and 13 per cent. of those delivered at term, showing the noxious influence of the bacterial toxins on the fetus. The practical conclusions from these experiences are to ward off interruption of the pregnancy and, in treatment of the influenza, to refrain from quinin and other drugs liable to stimulate the uterus to contract. The gynecologist should warn pregnant women to keep away from sources of contagion, and perhaps it might be wise to advise women not to become pregnant during a period of epidemic influenza, "although," the writers add, "this advice may elicit yelps of indignation from many persons."

The Gastric Mucosa with Ulcer.—Fricker reproduces four photomicrographs of the true pathologic anatomic findings which are the rule with ulcer. The mucosa shows a chronic inflammatory atrophy much more regularly than hitherto assumed. This imposes the necessity for careful and prolonged supervision of the diet after operative measures. In one case of chronically recurring peptic ulcer in a robust man of 43, the mucosa showed extreme hyperemia, and stasis hemorrhages were common, but there was no thrombosis or embolism and no signs of bacterial invasion. His micrographs were all obtained from the living mucosa, while previous research in this line has been on the cadaver or on animals. One conclusion is evident, namely, that more than one cause may induce peptic gastric ulcer.

- Necessity for Propaganda Against Tuberculosis. C. Molon.—p. 1041.
*Atypical Epidemic Meningitis; Two Cases. G. Salvetti.—p. 1043.

Atypical Epidemic Meningitis.—In Salvetti's two cases the onset was insidious, suggesting ordinary influenza at first. There was no vomiting, and the mind was clear throughout except just before death in one case. The temperature was always relatively low, and the lumbar puncture fluid seemed to be normal except for slight turbidity only at the first or second puncture, but the meningococcus was cultivated from the fluid in both cases. The fatal outcome in one case was a surprise after the extremely mild course in both.

- *The Facial Nerve in Epileptics. L. Roncoroni.—p. 3.
*Malarial Orchitis. E. Vecchia.—p. 6.
*Tuberculosis in Relation to Life Insurance. I. Romanelli.—p. 9.

The Facial Nerve in Epileptics.—Roncoroni calls attention to the hyposthenia of the innervation of the face in certain persons, saying that he has found it most pronounced in epileptics. Hyposthenia in other nerves may explain certain phenomena observed in other conditions, he suggests.

Malarial Orchitis.—Vecchia's patient was a youth of 16 with a history of old malaria, but no attacks for a year. Then suddenly intense fever and chills developed, with pain in the scrotum. Gonorrhea or mumps were suspected until the malaria parasite was cultivated from the blood, and under quinin the orchitis and the febrile attacks subsided.

Tuberculosis in Relation to Life Insurance.—Romanelli analyzes May's recent report on this subject, and compares the conclusions with his own experience, which suggests the advantage of postponing acceptance of a candidate who has recently had a tuberculous process in a bone or joint, in the urinary apparatus or peritoneum. In 75 per cent. of his cases, when pulmonary tuberculosis developed later the interval was not over three years. With a clinically cured pulmonary lesion, he warns that there may be still fire under the ashes, and a trauma or infectious disease may fan it into a flame. This occurred in many cases during the influenza epidemic. A ten year interval, however, is a good guarantee, other things being equal, with a progressively decreasing extra risk premium.

- Chaulmoogra Oil. A. Valenti.—p. 994.
*Ataxia of the Aorta. O. Cantelli.—p. 995.
*The Metabolism in Nephritis. A. Barlocco.—p. 1003.

Remittent Ataxia of the Ascending Aorta.—Cantelli applies this term to a set of symptoms observed identical in three cases. The symptoms were directly connected with transient disturbances in the innervation of the ascending aorta, the clinical picture being that of an aneurysmatic dilation of the ascending aorta: systolic fremitus, and harsh systolic murmur, heard in the second right interspace and spreading along the vessels, and a protodiastolic murmur of endoventricular origin, spreading to the apex, loudest at the focus for auscultation of the aorta. The assumption that the whole syndrome was of nervous, functional origin was con-

firmed by the abrupt subsidence of all the symptoms after a longer or shorter interval, and independently of any medicinal treatment. This behavior of the ascending aorta, especially when accompanied by symptoms resembling those of angina pectoris, bears the imprint of a sympathetic neurosis of that part of the vessel, in the same way as the attack of pain in the celiac plexus and pulsation and ectasia of the abdominal aorta represent the principal manifestations of the sympathetic neurosis of this part of the body. His patients were a woman of 42 and two men of 60 and 34. In the woman the attacks had always occurred just before the menses, and there were other signs of vasomotor instability, tremor and tachycardia. The older man was a bon vivant, with some sclerosis of the myocardium, and only the complete subsidence of all the symptoms in two months and the return later of the whole syndrome, excluded actual aneurysm. The man of 34 had long had a mild syphilitic aortitis when suddenly the symptoms of ectasia of the aorta developed, with the other signs described above, but all disappeared in twenty days without leaving a trace, after absolute repose was enforced, with a suitable diet. Cantelli devotes nearly nine pages to discussion of the mechanism, emphasizing anew in conclusion that the ataxia subsided in all his cases without any drugs.

Metabolism in Nephritis.—Barlocco reviews what others have been doing in study of the intermediate and external metabolism by Bang's micromethods applied to the blood. He compares with their results his own findings in a number of healthy controls, and in ten patients with nephritis studied daily till death. With sound kidneys the total nitrogen in the blood ranged from 0.027 to 0.046 per cent. and the urea nitrogen from 0.013 to 0.027 per cent. The ratio between the two, dividing the urea nitrogen by the total nitrogen, was between 35 and 60 per cent. The ureosecretory constant ranged from 0.062 to 0.106. In health, 15 gm. of urea, added to an ordinary diet, is eliminated in twenty-four hours. The chlorids in the blood amount to 3.20 or 3.80 per cent. and the glucose to 0.075 or 0.120 per cent. The differences between these figures and those obtained in his numerous cases of various forms of nephritis are discussed, as they serve to distinguish the different types. They emphasize the folly of attempting to study a case of nephritis from the whole blood or the urine alone.

Gaceta Médica de Caracas

Nov. 30, 1920, 26, No. 22

*Phlegmasia Alba Dolens in Typhoid. Villegas Ruiz.—p. 235.

Phlebitis in Typhoid.—Villegas described two cases of phlegmasia alba dolens which developed during convalescence from typhoid, the only instances of the kind he has encountered in his thirty-two years of practice and his hundreds of typhoid cases. The left thigh was affected, and in Murchison's fifteen cases the phlegmasia was on the left side in fourteen. In the discussion that followed, four other physicians referred to a total of seven cases in their practice. Villegas mentioned also phlegmasia of other origin; he has encountered a comparatively large number of puerperal cases. In certain other cases the phlegmasia was the warning sign of visceral cancer. In one case he accepted the phlegmasia alba dolens as pathognomonic of a cancer of the liver while other consultants insisted that the trouble was hypertrophic cirrhosis of the liver, but time confirmed his diagnosis. Trousseau diagnosed in himself the gastric cancer, to which he succumbed later, by the appearance of an insidious phlebitis in the dorsum of one hand. In treatment Villegas

has found electric light baths useful, but absolute immobility of the limb is the main thing. Tachycardia often occurs with the phlegmasia, and in Razetti's case the tachycardia persisted long afterward and the young woman finally died suddenly, possibly from embolism.

Prensa Médica Argentina, Buenos Aires

*Rupture of Bladder. A. F. Ceslea and A. Buzzi.—p. 225.

*Vicious Circle after Gastro-Enterostomy. N. Tagliavacche.—p. 226.

*Dissociated Elimination of Bile Elements. C. P. Waldorp.—p. 227.

Improved Slanting Curet. E. Finochietto.—p. 230.

*Arrhythmias. P. M. Barlaro.—p. 231. Conc'n.

Rupture of the Bladder.—The two cases reported by Ceslea and Buzzi were admitted to the hospital within twenty-four hours. The posterior wall of the bladder had ruptured in each case, in one from a fall, in the other probably in consequence of overdistention from fluid, self-injected, in treatment of acute gonorrhea. In this latter case no urine could be extracted with the catheter in the bladder, but in the other case the catheter had evidently found its way through the breach in the wall into the peritoneum, and quantities of blood-stained urine were evacuated. The shock and tenesmus were extreme in both, but a prompt laparotomy was followed by recovery.

Vicious Circle After Gastro-Enterostomy.—The man of 42 had had periods of gastric disturbance since the age of 20, and he finally had gastro-enterostomy done. This was followed by a period of tranquillity for seventeen months, when the disturbances began anew. An anastomosis between the afferent and efferent loops arrested the vicious circle, but a peptic ulcer with involvement of glands was deemed inoperable. The afferent loop was 30 cm. long, and the opening was not at the lowest point of the stomach and was too far to the left. Another defective feature of the technic was that the anastomosis ran from left to right.

Dissociated Elimination of Elements of the Bile.—Waldorp classifies the different forms of jaundice from complete or partial retention of all the elements of the bile and the jaundice with isolated retention of bile pigments or of bile salts. Hemolytic jaundice is the perfect type of the latter group, but it includes also catarrhal jaundice in the active stage, and some cases of jaundice from cirrhosis, or from infectious or toxic disease of the liver; it may possibly include likewise the early phases of the other group. With alcoholic cirrhosis there may be no sign of toxic retention as manifested by pruritus and bradycardia but the blood dust is scanty, and the Hay and Pettenkofer reactions are usually positive. Intercurrent infection or abuse of alcohol or other toxic action is liable to induce a phase of exaggerated retention and hence augment the jaundice temporarily. Brault and Garban investigated for retention of bile in long series of patients, and found it in some persons who gave no evidence of jaundice but had tuberculous, malarial or other form of liver disease. In typhoid also there may be retention of bile salts, with urobilinuria, as also in pneumonia in male adults, and in all persons with chronic poisoning from any cause. Brulé warns that retention of bile elements with appendicitis suggests that the liver is vulnerable, and hence should not be subjected to the strain of chloroform. The bile salts are also liable to be retained during pregnancy, the retention increasing as the pregnancy progresses, and ceasing after delivery.

The Arrhythmias.—Barlaro entitles his article a "brief" study of the arrhythmias, but it has been continued through a long number of issues. He recalls that treatment must be based on the special form of the arrhythmia and on the occasional cause. To illustrate the imperative necessity for seeking the cause he tells of a case in which an attack of fainting, palpitations, arrhythmia and bradycardia resisted the entire battery of heart tonics and stimulants but subsided promptly under a purge and restriction to water, a dish of green peas being responsible for the whole disturbance. In one woman the diagnosis of myocarditis as responsible for the arrhythmia was changed later to arrhythmia from impacted gallstones, and extraction of the stones put an end

at once to the arrhythmia. Besides removing the cause and treating stomach, bowel and gynecologic disease which may be a contributing factor, it may be wise to soothe the over-excitable nervous system and give tonics. Valerian and belladonna are often useful, the latter reducing reflex action from the stomach, the most frequent cause of extrasystolic arrhythmias, while it moderates the excitability of the heart. Heart tonics are liable to exaggerate the arrhythmia, but in paroxysmal tachycardia, digitalis well managed may give fine results, as also strophanthin with pulsus alternans and perpetual arrhythmia. Organ extracts may prove surprisingly effectual in appropriate cases, and antithyroid serum with hyperthyroidism. If the dropping of tea, coffee or tobacco is not soon followed by improvement, the cause must be sought elsewhere. Brilliant cures may be realized with mercury and iodid when syphilis is responsible, and the latter drug may render good service with sclerosis in vessels or elsewhere. In some cases tuberculin may prove extremely useful. With paroxysmal arrhythmia, drinking or eating something may help in arresting an attack, by the reflex from swallowing; or compression of the pneumogastric nerve may stimulate it to inhibit the excessive action of the heart. Tickling the pharynx or other means to induce nausea and vomiting may arrest the attack in some persons; in others this may aggravate it. The condition of the heart muscle must be supervised, and venesection, revulsion, purges, and diuretics applied as indicated.

Reforma Médica, Lima

October, 1919, 5, No. 62

*Treatment of Eclampsia. P. Villanueva.—p. 116.

Eclampsia.—Villanueva as a last resort in a case of convulsions from uremia in a man of twenty-eight with advanced chronic nephritis, injected sodium bicarbonate by the vein. The result was surprisingly good, the convulsions subsiding, and the acute phase was soon past. He applied this same treatment in a case of puerperal eclampsia in which the convulsions and anuria had kept up after venesection and evacuation of the uterus. Four hours later the convulsions abated, the catheter drew 150 gm. of urine, and the general condition seemed more hopeful, showing that at least the 50 gm. of the saturated solution of sodium bicarbonate by the vein had done no harm. He repeated the infusion, giving 100 gm., and applied lumbar puncture. By the next morning the patient was out of danger. This experience has been confirmed in eleven other cases in the last five years, prompt improvement following the combination of venesection, lumbar puncture and the alkaline infusion, with copious intake of fluids. He urges others with laboratory equipment to confirm his merely clinical assumption that acidosis is responsible for eclampsia, at least in certain cases.

Repeated Laparotomy. A. Morales.—p. 1114.

*Essential Incontinence of Urine. F. González Aguilar.—p. 1116. Concluded in No. 3449, p. 37.

Incontinence of Urine.—González reiterates that thorough study of the child will almost invariably reveal some explanation for the enuresis in some hitherto overlooked disease or some anomaly that may possibly be corrected. Only when all such can be positively excluded are we justified in labeling the case as essential incontinence. Treatment should aim to reduce the irritability of the bladder or stimulate the atony of the sphincter, according to the case. The diet should be extremely nourishing and digestible, and of the smallest bulk possible. Overstarched or overtight clothing, powder-

ing, and dirt may maintain the tendency to incontinence. In two of his cases it was cured by constant vigilance rendering masturbation impossible. He lauds epidural injection of physiologic artificial serum as one of the most valuable measures in treatment of enuresis, and never hesitates to apply it when belladonna, strychnin and electricity fail. Any practitioner, he says, can give the epidural injections, using from 5 to 10 c.c.; for children under 12 not more than 3 c.c. Inunction in the pubic region twice a day of a drug to soothe the peripheral nervous system has sometimes aided. Courtade has reported 55 per cent. cured and 85 per cent. much improved by the induced electric current, but González advises reducing the intermittences to one a second. This stimulates instead of fatiguing the muscles, and he always is guided by the patient's tolerance. He applies the electricity for five or six minutes every day at first, and later every second or third week. In concluding his long study of incontinence, he mentions Bonnier's success in otherwise intractable cases by modifying the excitability of the bulb by cauterizing certain portions of the nasal mucosa.

The Capillary Pulse in Infectious Diseases.—From a series of observations Lichtwitz reaches the conclusion that the capillary pulse in fever is not the result of increased heart activity, elevated temperature, or rubedo, but is due to a disturbance of peripheral circulation in the region of its appearance brought about by a toxic injury of the arterioles and capillaries. He was not able to discover that the phenomenon has any prognostic significance.

The Use of Orthoform in Psychiatric Cases.—Böttcher has found orthoform of great value to allay itching in pruritus vulvae et vaginae in psychiatric cases. He uses ordinarily a 10 per cent. ointment. The anesthetic effect of the orthoform continues for from ten to thirty hours, which is a valuable feature in dealing with psychiatric patients, who become impatient and work harm to themselves if the itching is not promptly allayed.

Recent Problems in Paralysis and Tabes Therapy.—Plaut says that the fact that familial paralysis and tabes are comparatively rare is opposed to the assumption of a peculiar type of spirochete the mere presence of which in a subject would cause syphilitic paralysis or tabes. The changes that regularly occur in the spinal fluid during the secondary stage of syphilis are usually followed by normal conditions, whether specific treatment is given or not, so that it hardly seems likely that these changes are to be regarded as the foundation for the later development of paralysis or tabes. In the case of a few syphilitics, however, the spinal fluid continues to show pathologic changes even after many years. Whether the paralytics develop from this class can only be shown by a long series of investigations. He avoids mercury entirely in the treatment of paralysis, and for the treatment of tabes he prefers salvarsan to mercury. Salvarsan is ordinarily not indicated in syphilitic paralysis, as it does not stay the progress of the disease, but, he thinks, it may be well to use it in the initial stages owing to the danger of a false diagnosis of paralysis being made when in reality

it is a genuine case of syphilis of the brain. He denies that salvarsan used in syphilitic paralysis causes paralytic attacks, untoward mental and physical reactions, and even symptoms resulting in death. One symptom of paralysis usually yields to salvarsan, that is, the increase in the number of cells in the spinal fluid. Intraspinal injections in syphilitic paralysis have not proved effectual, he continues. In tabes, however, intraspinal injections exert a favorable influence on the pain, the crises, paresthesia, bladder trouble and ataxia, and should be used unless intravenous therapy, which should always be tried first, has already brought about reasonable symptomatic improvement. Whether intraspinal mercurial treatment will prove efficacious in paralysis and tabes remains to be seen. The fact that paralytics often receive at least temporary benefit from induced febrile processes has long been known, and of late Vienna physicians have scored considerable success in this mode of treatment. Plaut has seen no noteworthy improvement following the use of vaccines in syphilitic paralysis and, in general, the results of the various forms of treatment in paralysis and tabes are far from satisfactory, but with earnest collaboration of clinicians, experimental pathologists, anatomists, serologists and chemists, he hopes for progress in the future.

The Pathogenesis and Treatment of Bed Sores.—The matter of bed sores has been left too much to nurses, Wieting thinks, and many physicians are inclined to assume an indifferent attitude, from which great harm results. His investigations as to the fundamental origin of bed sores have led him to the conclusion that the pressure causing the necrosis or gangrene is exerted from within and not from without, as is commonly supposed. Aside from cases in which the epidermis or cutis has been injured directly by thermic, chemical or mechanical causes, only disturbances of the blood supply can bring about necrosis of the skin, and these disturbances are caused by the more or less complete occlusion of blood vessels by pressure continued too long in one spot, whereby an anemic condition of the more sensitive subcutaneous and deeper-lying tissues is effected. It is evident, therefore, that the subcutaneous tissues suffer more and earlier than the skin; their necrosis precedes that of the skin. While admitting that there are cases in which decubitus cannot be avoided even with the best of care, he believes that many cases that occur are avoidable. Besides the ordinary measures—such as change of position, absolute cleanliness, rubbing with alcohol, the use of rubber rings, water cushions, underlay of cotton—he thinks more recognition should be given to the continuous water bath in the more serious cases. The patient may be suspended for hours at a time in a warm bath, in which he is supported by a bed sheet or a hammock. Frequently suspension apparatus may be indicated, as in the case of wounds of the heel or the lower leg. In the matter of bed sores hypurgia plays a big part, that is, the sum of the minor factors that make for prophylaxis and recovery. Even the placing of a rubber ring cushion so that the pressure will be taken off a certain spot is not such a simple matter as it may seem to some.

The Effect of Influenza on Pregnancy.—Schmitz reports that in Germany it was often noted with surprise that the strongest persons seemed to have no more, but perhaps even less, resistance than the weaker. He takes this as only an indication how primitive our ideas are concerning the meaning of the term "constitution." We are too much inclined to assume that a sturdy frame and a well developed musculature must necessarily presuppose extra resistance of the organism to infection. Our knowledge of individual differences in matters of morphology, the ability of cells to react, and the ever changing content of protective substances in the body fluids is still too indefinite for us to do more than speculate in regard to comparative immunity. An illustration of this is Fischer's assumption that sturdy persons have too many antibodies, and that their lack of resistance is due to the fact that they kill off the invading germs too rapidly, and thereby overload the body with liberated toxins, or Grabisch's hypothesis that healthy persons have less capacity to produce antibodies because they are, in the nature of the case, less exposed to infections. On the other hand, the effect

of pregnancy on the course of influenza is not a matter of speculation. It is entirely too evident. Of thirty-seven pregnant women in his service, nearly 46 per cent., died. The mortality among the nonpregnant was only 12.5 per cent. Aside from the changes in the respiratory mechanism and the impeding of the circulation, Schmitz thinks that one possible explanation of the unfavorable effect of pregnancy on influenza lies in the physiologic swelling in pregnancy of the mucous membrane of the respiratory organs.

Scleroderma in Relation to Disease of Endocrine Glands.—Roesch reports a case of generalized scleroderma, in the indurated stage, in a young woman with symptoms of abnormal thyroid and suprarenal functioning. He concludes therefore that scleroderma may possibly be caused by disturbances of function in one or more of the glands of internal secretion.

Treatment of Emphysema.—Heermann recommends, as an effective therapeutic device in emphysema, an elastic rubber bandage, from 4 to 5 cm. wide, buckled about the chest at the level of the short ribs. He finds it aids expiratory movements and produces a feeling of comfort and relief. It is worn during the day—continuously, if possible. The good effect is soon shown by the increase in lung expansion and the remission of symptoms in the lungs and throat.

Chronic Lethargic Encephalitis.—Economo reports a case of lethargic encephalitis in a man of 45, which ran a long course, from April 5, 1917, to Jan. 7, 1919, when death ensued. The onset was acute. Periods of remission occurred, only to be followed by ever more violent attacks. The clinical diagnosis was pseudobulbar paralysis, with athetosis, following lethargic encephalitis. The necropsy findings were: hypostatic pneumonia in the right inferior lobe, atrophy of organs, parenchymatous degeneration of the myocardium, cachexia, no macroscopic changes in the central nervous system. The microscopic examination revealed extensive evidence of a poliomyelitis. In addition to the older lesions, there were several recent lesions of an acute type. Economo assumes that the virus of lethargic encephalitis after the first acute attack was not completely eliminated but continued to act on the central nervous system, setting up a chronic condition, with occasional exacerbations, carrying on its gradual work of destruction resulting in death. He compares the case to the rare cases of chronic anterior poliomyelitis following the acute form. It also seems to throw a sidelight on multiple sclerosis. Economo refers also to a mild epidemic of lethargic encephalitis that occurred in Vienna nearly two years before the first wave of the influenza epidemic, which, he thinks, supports the idea that it is a distinct disease, and refutes the claim that it only follows influenza. It would be a serious mistake to term the disease influenzal encephalitis as its causal connection with influenza is still uncertain.

Favorable Effect of Roentgenotherapy on Retarded Growth.—Stettner states that in cases of retarded growth due to disease such as chronic parotitis, or to constitutional anomalies such as status lymphaticus, he has been able, within a few months, to make up for a deficiency equal to several years of normal growth. In the two reported cases the retarded growth manifested itself in the lack of ossification centers; in one the bones had developed normally in length. In both cases the incited growth was accomplished by means of roentgenotherapy applied to the head, and doubtless particularly affecting the hypophysis in one case. The condition

of the bones of a child as shown by roentgenograms is a factor to be weighed in judging of the child's general condition. Stettner considers his results important as indicating the possible effect of roentgen rays on the organs of internal secretion. Three and five sittings were given in the course of four months and seven months, respectively.

Influenza in Relation to Pulmonary Tuberculosis.—Amelung's observations and investigations lead him to conclude that the influenza morbidity among patients with pulmonary tuberculosis is slight; that influenza takes a milder course in such patients than in the nontuberculous, unless the tuberculosis is far advanced; that tuberculosis of the lung may and sometimes does follow influenza in patients whose lungs were previously sound, and that in the last mentioned cases the prognosis is relatively bad. A theoretical explanation of the reciprocal relationship that exists between influenza and tuberculosis may be that the organism of tuberculous patients is from the start in a state of defense, whereas the healthy subject is taken unawares in a state of unpreparedness, and is swept away before he can mobilize his antibodies.

Utilization of Surplus Human Milk.—Marie Kayser describes in detail a system introduced in Magdeburg during the war by which surplus human milk was collected in the homes and utilized in hospitals and elsewhere for feeding to weakly and needy infants. The milk of healthy mothers, only, was used. In the nature of the case, Wassermann tests could not be made, but as the milk was always carefully boiled before it was used, it was assumed that infection was no longer to be feared. Boiling lessened the value of the milk so collected, but it was in any event better than boiled cow's milk for the infants for whom it was utilized.

The Composition of the Blood in Arid Climates.—Bickel, Loewy and Wohlgemuth refer to Grober's article on this subject, an abstract of which appeared in *THE JOURNAL*, Jan. 31, 1920, p. 365. From his examination of the blood of natives of Tunis, Grober had reached the conclusion that such a thing as urinary substances being given off from the blood in secretions, for instance, through the sweat glands, was an impossibility. Bickel and his co-workers state that Grober's conclusion was not justified. The fact that the blood of natives of Tunis is essentially the same in its composition as that of Europeans living in Europe is no proof, they think, as to whether or not the arid climate has any effect on the blood, much less that it may not exert a definite effect on metabolism which is concealed by compensatory processes in the blood. For example, it might well be true that marked changes occur in the sodium chlorid output and in the nitrogenous waste eliminated from the blood, while the blood still retained its usual percentage of these substances. Furthermore, there might be marked shifting in the proportionate amount of urinary substances eliminated by the kidneys and the skin, without evidence of this fact being necessarily present in the blood. In order to decide such questions as these, concurrent investigations on metabolism should be made; quantitative determinations of the elements of the urine, and also determinations of the amount and composition of the skin exudations, with due consideration of the nature of the food consumed. They also think that Grober should have examined the blood of Europeans living in Tunis, in order to draw just conclusions as to the indications of arid climates for Europeans suffering from kidney disease.

- Treatment of Sprained Ankle. K. Gerson.—p. 438.

One-Sided Diets.—Jacoby remarks in concluding his study of this subject, that the terms vitamins, nutramins and accessory nutrients are about synonymous with each other,

and with oryzanin. Eutonin seems to be the organic base which is the mother substance of the others.

Treatment of Diphtheria.—Albrecht suggests that Bingel's plea to use normal horse serum, instead of antitoxin, has served to focus attention anew on the great changes induced in the organism by serum alone. But it has served most of all to emphasize anew the immense value of antitoxin, and that nothing can approach it.

The Alcohol Question.—Waldschmidt agrees with those who think that some inherited predisposition turns the scale so that one person becomes an addict and another not. The drunkard is "born, not made." The sound brain repudiates the abuse of alcohol. From prehistoric times and in all races there have been stimulants of different kinds, and it seems as if the human race cannot get along without them, but the more dangerous ones, he insists, should be prohibited.

- *Treatment of Fractures in the Aged. C. Heinemann.—p. 335.
- Whooping Cough. A. Kötze.—p. 341.
- *Acute Addison's Disease Following Influenza. Brünecke.—p. 354.

Treatment of Wounds.—Loewe and Magnus present a long series of arguments striving to restore a more pharmacologic view of the treatment of wounds, instead of the excessive bacteriologic view that has prevailed of late.

Fractures in the Aged.—Heinemann tabulates the details of twenty-two cases of fracture, mostly of the femur, in men and women from 61 to 78 years old. He affirms that the physician's task is more to keep the aged patient alive, than to cure the fracture. The patient must not be chained to the bed for more than a few days at most, consequently, a light plaster cast is preferable for immobilization. It should leave as much of the limb free as possible. When the fractured stumps have been driven into each other, a cast may sometimes be dispensed with; the patient can be got up with crutches or a walking frame. The getting the patient out of bed is the main thing, after the first shock is past. Lying in bed mechanically impedes the functioning of the autonomic system, and depresses the vital energies. In other pathologic conditions, the elderly can keep fairly well, even lying in bed, by exercising the legs and arms while reclining, but this is impossible with a fractured limb. Systematic breathing exercises, after the patient is up, help to maintain the circulation and ward off atrophy, and they benefit in other ways. Tepid baths under medical oversight are also useful. In his 22 cases a complete functional cure was realized in 11, and improvement in all the others, except in one fatal case of fat embolism. This patient, a woman of 62, had been long kept in bed after the lengthwise fracture of the femur. Only 7 have to use a cane, and 2 others, one or two crutches.

Acute Addison's Disease After Influenza.—Brünecke reports this case to call attention to the prompt benefit from treatment with partial antigens. Tuberculous lesions in the glands in the neck had suggested the advisability of this treatment for the girl of 12.

- Treatment of Old and Ulcerating Wounds. H. Deutsch.—p. 1157.
- *Observations on Ophthalmomyiasis. W. Goldschmidt.—p. 1159.

Roentgen Treatment of Hypertrichosis.—Holzknecht discusses the psychologic reasons why hypertrichosis in women should be treated, and describes in detail his method of roentgenotherapy with which he has been very successful. In some of the cases he describes, the women had tried to commit suicide on account of the disfigurement from the growth of hair on the face.

Treatment of Gunshot Wounds of Joints.—Salzer states that since there is no uniform method of treating joint

injuries, it is desirable that surgeons should give the results of their experiences in this field of surgery in order that out of the common experience of all a uniform method may be gradually worked out. In gunshot injuries of joints in which the bones were not seriously involved and in which the wounds had closed without reaction, he proceeded as follows: The joint was punctured and the fluid was drained off; from 3 to 5 c.c. of tincture of iodine was then injected and a light protective bandage was applied. This procedure was repeated, if necessary, two or three times. In 14 cases of gunshot wounds of the knee joint treated in this manner the patients were dismissed in about twelve days, the joint showing a good degree of motility. In one case, however, suppuration developed, rendering an operation necessary. On the other hand, if the wounds were lacerated and oozing, thorough débridement was done, the joint was cleansed with sodium chlorid solution, then completely sutured and tincture of iodine injected. After about sixteen days 7 such cases were dismissed in good condition. In another case, however, sepsis and periarticular abscesses occurred, which necessitated amputation at the thigh. In this case, owing to the pressure of work at the front, through an oversight, débridement and suturing of the wound of entrance had not been done. A total of 40 joint wounds (38 knee joints, one elbow and one shoulder joint) came up for treatment. In 3 cases primary amputation was required; in the other 37 cases the simple method described above was employed. In 7 cases secondary amputation became necessary. The remaining 30 were dismissed with fairly movable joints. There were no deaths. The last fatal case resulting from a joint injury dated back to the time when, though tincture of iodine was employed, primary suturing of the wound was not undertaken. While admitting that the results were not ideal, Salzer maintains that they were at least much better than had been secured under the conservative treatment. An important advantage of this method was that the patients suffered much less pain.

Foreign Body Arthritis.—Hirsch reports a case of arthritis of twenty years' standing due to the presence of a fragment of a needle in the knee joint. In spite of the fact that the joint had been frequently swollen and painful, after the needle was removed complete recovery followed in four months. Hirsch concludes, therefore, that in any disease affecting the knee joint the presence of a foreign body should be given diagnostic consideration. In his case the arthritis had been first of the intermittent hydrops type and later of the spongy, granulation type. This latter aspect should suggest the possibility of a foreign body.

Ophthalmomyiasis.—Goldschmidt describes his experience with 100 cases of ophthalmomyiasis in a river region in Russian Turkestan, central Asia. In the summer of 1915 a prisoner of war presented himself complaining of a foreign body in the left eye. The eyelids were swollen and inflamed. Examination revealed living organisms in rapid motion spread over the surface of the conjunctiva. There were from eighteen to twenty of such yellowish white organisms of varying length (from 0.25 to 1.5 mm.). Most of the larvae were removed by rinsing out the eye. Some of them, however, had burrowed into the cornea, and had to be removed with a swab, which was only possible after cocaine had caused them to loosen their hold. The patient developed, as a result, a keratitis with hypopyon, which healed leaving maculae and synechiae. The larvae were preserved in alcohol and were pronounced by Dr. Kuznetzoff, a Russian physician who had been practicing in the vicinity for a number of years, to be *Sarcophila magnifica Schineri (Wohlfarti)*. Goldschmidt had occasion to remove similar larvae from the eye in 100 other cases and learned that this ophthalmomyiasis was not uncommon. He says that a fly in its flight will often scrape off from sixty to seventy larvae onto the eyelid. The larvae display a tendency to burrow into the eyeball, and have been known to destroy it completely within forty-eight hours. Or after weeks of suppuration the end-result is atrophy of the eyeball, which is permeated with scars. Kuznetzoff had not known of any fatal cases such as have been reported by others, resulting from pyemia and sepsis.

Zentralblatt für Chirurgie, Leipzig

Jan. 17, 1920, 47, No. 3

*Headache After Intraspinal Medication. G. Hosemann.—p. 49.

*Blocking the Splanchnic Nerves. A. Hoffmann.—p. 53.

*Sound for Stenosis of Esophagus. E. Borchers.—p. 54.

By-Effects with Spinal Anesthesia.—Hosemann explains that the persisting headache after spinal anesthesia should always be analyzed as it may be due to one of several causes. In 17 per cent. of his 100 cases it was explained by irritation, meningism; the fluid was always under high pressure, with high albumin and cell content. Treatment here is with repeated lumbar puncture, diuretics and purges. In the other 83 per cent. the fluid was under very low or negative pressure, and there was very little albumin or cell content. The above mentioned measures would only aggravate conditions here. Copious intake of fluid is required here, better by the vein than subcutaneously or by the rectum. This will cure the headache within a few hours while under other measures it is liable to persist for weeks.

Blocking the Splanchnic Nerves.—Hoffmann joins in the chorus of praise for Kappis' method of blocking the splanchnic nerves from the rear for abdominal surgery. (The technique was described in these columns, Feb. 21, 1920, p. 568.) He has been using it for nearly a year for all kinds of operations on the stomach, duodenum, bile ducts, etc. A weaker solution of procaine answers the purpose, he says, and he advocates adding a little potassium sulphate: 0.5 parts procaine; 20 parts of a 2 per cent. solution of potassium sulphate and enough of the 0.9 per cent. solution of sodium chlorid to make 100 parts, adding 12 drops of 1:1,000 epinephrin.

Dilation of Cicatricial Stenosis.—Borchers expatiates on the advantages of the special sound he uses for this purpose. It is 1.5 meters long and tapers smoothly from 1.5 mm. at the tip to 1 cm. at the base. It is used in connection with the endless silk thread drawn out through an opening into the stomach, in correction of stenosis of the esophagus.

*Treatment of Postoperative Tetany with Parathyroid Grafts. F. Landois.—p. 74.

*Removal of Half of Horse-Shoe Kidney. G. Magnus.—p. 76.
Technic for Correction of Equinus Contracture after Amputation of Tarsus. A. Wachter.—p. 78.

Transplantation of Parathyroids in Treatment of Tetany.—Landois' experiments with parathyroid grafts in thirty-five dogs showed that only the autoplasmic operations were successful, and not all of these. Even at the best, the transplanted parathyroids have only a transient functional action, as they are soon absorbed. At the Breslau clinic there was only one case of tetany after thyroidectomy in ten years, but then came five cases in the last five years, fatal in one instance. As the spasms were continuous and the man was unconscious, three parathyroids were implanted, and essential improvement followed at once. It lasted, however, only nine days; the spasms then returned and soon proved fatal. Landois reiterates in conclusion that the parathyroids are not secreting organs, but glands which serve to neutralize the toxicity of certain injurious substances in the body. Hence treatment with parathyroid has little chance of success. Any treatment with established tetany is uncertain.

Heminephrectomy of Horseshoe Kidney.—Magnus found that the tuberculous process was limited to the right half of the horseshoe kidney, and he resected this alone. There was surprisingly little hemorrhage, and clinical recovery soon followed. The abnormal shape of the kidney was not suspected until it had been exposed.

Transverse Septum in Vagina Impeding Delivery. T. Micholitsch.—p. 84.

History of Experimental Hermaphroditism. A. Foges.—p. 87.

Central Placenta Praevia.—Mathes knows of only twenty-two cases of placenta praevia centralis on record and adds another to the list. The fatal hemorrhage in such cases usually comes on separation of the placenta, so that the third stage of labor is the dangerous one here. He pleads for more energetic management of the case, pointing to his success with tying a thread around the tissues, just above each bleeding point, after the cervix had been opened up wide with speculums, after removal of the placenta. The placenta had been easily removed from above the cervical ring; below this it had to be pried loose, a scrap at a time. The hemorrhage at first had been so severe that the idea of cesarean section had to be abandoned as there was no time to prepare for it, and drawing down the foot arrested the bleeding. Waiting for the placenta to separate spontaneously, he says, has cost many lives, but with this method no fatal hemorrhage should occur from this cause, in a maternity at least. Pituitary and ergot should be given to insure good contraction of the uterus, the placenta then separated by hand under direct visual inspection, and each bleeding point tied off with a thread run around centrad.

*Carcinoma Dose of Roentgen and Radium Rays. L. Seitz and H. Wintz.—p. 97.

Exudates in Pouch of Douglas with Appendicitis and Adnexa Disease. A. Mueller.—p. 109.

*Laminaria. K. Hoffmann.—p. 111.

The Unit of Cancer-Cell Destroying Action in Irradiation.—Seitz and Wintz have been studying the amount of roentgen and of radium rays required to destroy the cancer cell. They call this the carcinoma dose. It is equivalent to 100 to 110 per cent. of the skin unit dose (H. E. D.) which they accept as the amount of rays with 0.5 mm. zinc filter which, applied at a distance of 23 cm. from the skin, induces slight redness after eight days and a brown tint by the third to sixth week. Calling this 100 per cent., the carcinoma dose is 100 to 110 per cent.; the lowest limit is 90 per cent. It thus corresponds to the older conception of the erythem dose, but it does not vary, like the latter, with the susceptibility of the skin. Radium causes rapid necrosis of the cancer cell, while the destructive action of the roentgen rays is slower and more gradual, but the final result is the same with both, although the radium action is a close-up and the roentgen action a distant one. To destroy a cancer of the cervix over an area 3 cm. in circumference requires about 100 mg. radium element for thirty-two hours. When the amount of radium element was increased to 140 mg. and the exposure lengthened to thirty-four hours, with a 3 cm. cancer, the rectum suffered and a burn resulted. On account of the close contact and the biologic effect, the dose cannot be estimated by mathematical calculation as it might be if the distance were the same as with the roentgen rays. They advise that the dose of 100 mg. radium elements should not be surpassed unless the tumor is larger than 3 cm. and the bladder and rectum are thus pushed farther away, to a distance which weakens the effect of the rays, so that the sound tissues are left still capable of regenerating. To increase the distance, they keep the gamma ray filtered preparation in a wooden capsule, 4 to 7 mm. thick, with a thin coating of aluminum, and a glass cover. This holds the radium about 10 mm. apart from the tissues, and sometimes the cervix has to be dilated to introduce this bulky capsule.

Removal of Laminaria.—Hoffmann passes a loop of stout cord horizontally around the end of the tent as this projects from the cervix. Tweezers or some other small instrument is tied to the ends of the cord projecting from the vulva. By this firm hold and cross-bar handle, the laminaria can be easily pulled out.

*Otitis Media and the General Practitioner. R. Bárány.—p. 81.

Otitis Media.—Bárány insists that the symptoms from acute otitis media which call for immediate operation during the third week do not have this significance during the first week. Only when they keep up after paracentesis, and grow worse, is the operation demanded. The bone is still hard, and to get into sound bone merely spreads infection. It is better to wait till the third or fourth week unless chills or meningitis force earlier intervention. The practitioner must realize further that there may be a destructive process in the mastoid process from an otitis media that has never required paracentesis. The ear may have healed while the mastoiditis is progressing. If the mastoid is tender from the start, the probabilities are that an operation will be necessary, but this is not inevitably the case. In one woman of 50 with 8 per cent. sugar, a large abscess in the mastoid process accompanied otitis media, and the auditory canal was filled with pus and granulations. The ear was treated with Burrow's solution and thorough rinsing, while the sugar was being reduced with antidiabetic diet, to prepare for the operation. But in two weeks the abscess had disappeared and the hearing and the drum seemed to be normal. The physician should therefore be guarded in his prognosis, but the possibility of the bacteria dying off and the abscess healing spontaneously is too remote to deter from operating. Even with paracentesis he advises to temporize for a few hours, as spontaneous improvement may be observed. High fever in children in itself does not demand an immediate operation. In treatment of otitis media, he advises thorough but gentle rinsing out of the ear, saying that he does not think it possible for water to be forced into the internal ear, by this means, so that the dread of inducing labyrinthitis or meningitis is unfounded. He warns, however, that no water must be left in the ear as this provides a culture medium for germs. After rinsing, the ear must be thoroughly dried with cotton.

After the operation, he sutures the wound except for one small opening which he plugs with a rubber finger stuffed with gauze. This cigarette tampon is removed the next day, and a drain is inserted in its place made of rubber tissue rolled into a 2 or 3 mm. thick drain, which answers the purpose ideally. With chronic otitis media, the main contingents for operation are cholesteatomas in the middle ear, and for this he applied what he calls the "conservative radical" operation in 70 per cent. of his fifty-five cases and the hearing was considerably improved in all but two instances. This technic is being applied now extensively in other clinics.

*Treatment of Sterility in Women. C. Baastrup.—p. 111.

Treatment of Sterility in Women.—Baastrup is convinced that excessive acidity of the vaginal secretions may be responsible in some cases for sterility, by injury of the spermatozoa from the overacid environment. This assumption was confirmed in one case by conception following the use of a vaginal douche of a weakly alkaline fluid: a tablespoonful of a 2:1,000 solution of sodium hydroxid in a pint of tepid water.

Correction.—In the abstract on page 1860 of THE JOURNAL for Dec. 13, 1919, from Tecon's article on "Trauma and Tuberculosis," part of a sentence was left out by mistake. The sentence should read: "Sergent and Mantoux found only 9 and 5 per cent. with pulmonary tuberculosis after contusions and penetrating wounds of the chest while Tecon's proportion was 42 per cent." The italics are the missing words. The proportions after contusions alone were 55.5, 38.9 and 60 per cent., respectively.

THE INCIDENCE OF ACUTE RHEUMATIC FEVER AT BELLEVUE HOSPITAL*

ALEXANDER LAMBERT, M.D.

Visiting Physician, Bellevue Hospital

NEW YORK

On returning in the spring of 1919 to service in the wards of Bellevue Hospital, after a two years' absence, I was struck by the fact that there were no cases of acute rheumatism in the service. My memory was that spring and summer were the months when formerly there had been the largest number of cases. The house staff, on being questioned, seemed to accept it as not unusual; and though their memory dated back but two years at most, still it was evident that they were accustomed to the occurrence of fewer cases of the disease than had been my own hospital experience.

There were admitted into Bellevue Hospital 6,535 cases of acute rheumatic fever from January, 1906, to Sept. 1, 1919. Unfortunately, the records of the last four months of 1919 are still incomplete for the moment. In dealing with any hospital history records, with a varying house staff taught in three different schools of medicine in New York City and in the open division, coming from several widely separated schools over the United States and Canada, one would expect to find a certain variation of opinion as to what clinical picture would be recorded under such a general heading as acute rheumatism. But in reading the histories one finds it generally accepted, with few exceptions, that classified under rheumatism is the inflammatory

joints and without cardiac valvular involvement. Only a very small percentage will strike one as more fittingly to be classified from arthritis to acute rheumatism or vice versa. The number of cases of arthritis five and six years ago were about one quarter those of rheumatism, but during the past four years the number of rheumatism cases has diminished and the number of arthritis cases increased until in 1918 there were slightly more cases of arthritis than of rheumatism, there being 218 cases of rheumatism and

TABLE 2.—RELATION OF RHEUMATIC FEVER CASES TO TOTAL ADMISSIONS

226 of arthritis. Table 1 shows the number of arthritis cases since 1912.

This classification also rules out the number of arthritis deformans, the chronic arthritis and the gonorrheal joint infections.

In studying the rheumatism cases tabulated by year for age and total number (Tables 2 and 3), it is seen that in 1907 the percentage of acute rheumatism cases to the total admissions was 2.45 per cent. From that year the percentage has fluctuated slightly, but it steadily diminished to 1918, when it was 0.531. The total number of rheumatism cases had fallen from 706 to 218, and the total admissions had increased from 28,789 to 40,980. From 1909 through 1914, the number of rheumatism cases ran from 599 to 432, and the total admissions from 31,652 to 37,162, with practically a stationary ratio to total admissions, that of 1.6 per cent. But from 1915 for the next four years, the total admissions to the hospital increased greatly, and the number of cases of rheumatism diminished, so that the ratio to admissions becomes 1.02, 0.896, 1.03, 0.531 and 0.521 per cent. In 1919 we have the actual number of admissions for acute rheumatism for the first nine months of the year; but in calculating the total for

arthritis with fever affecting two or more large joints and frequently showing cardiac manifestation. The arthritis affecting the smaller joints of the hands and feet or affecting only one large joint are classified under arthritis, or knees and ankles affected with but little if any fever. Conversely, in studying the histories of arthritis one is struck by the unanimity with which acute arthritis refers to traumatic injuries to single joints or the inflammation of single joints, non-traumatic, or the acute multiple arthritis of the smaller

1919, the actual admissions for the last four months of each year for the preceding five years were taken as a standard. From these figures it is evident that 11 per cent. of the total admissions for each year for rheumatism have been admitted during the last four months of the year. During the previous three years

averaged about the same. For all ages under 20 years, the percentage of these ages to the total has distinctly increased, as the total number of cases of rheumatism has diminished. Young persons from 20 to 24 and from 25 to 29 show a greatly diminished actual number of cases admitted, and in the last two years, 1918

table further shows that rheumatism is noticeably more prevalent from March 1 to August 1 than in the other months of the year, showing the disease to be one of spring and summer predominance. This tends to disprove the "chill" theory of causation as brought forward by Cullen in 1778 and held until recent years. Hirsch shows that in Denmark and Germany the winter months of December, January and February show usually a higher incidence than spring and summer. Similarly separated into seasons, the Bellevue figures of 1915 through 1918 have a spring and summer excess except in the winter months of 1918 (Table 5).

Considering the relation of age to the occurrence of rheumatism, we have definite figures from 1911 to 1919. Divided in quinquennial periods from 5 to 9 and 10 to 14 years of age, the actual number of admissions of the 5 to 9 group has increased, but the 10 to 14 group has remained about the same, so that the percentage of the ratio of these years to the total admissions for the year has risen as the total number of admissions has decreased. From 15 to 19 years the actual number has diminished, but the percentage has

and 1919, a percentage fall also. From 30 to 39 years of age, the total number of admissions has fallen with but slight change in percentage to total cases. The same can be said for the years 40 to 59. There has been, therefore, a great diminution of the total number of patients with rheumatism admitted from 15 years of age on. Under 15 years of age the total number admitted has remained stationary. From 15 to 29 years of age, both the actual number of patients admitted and the percentage of these age groups to the total number each year has noticeably diminished, particularly in the years 20 to 29. From 30 years onward, the greatest change has been in a diminution of actual numbers.

EFFECT OF PREVENTIVE MEASURES

These changes are marked after the year 1914. Has any new factor appeared in the preventive measures against rheumatism since 1914? None, except the spread among the medical profession of realization of the relation of focal infections to general diseases; and it was about six years ago that the dental clinics were established in the various hospitals in this city and the tonsillectomy clinics became vigorously active. The foregoing figures would seem to indicate that in the years of childhood, from 5 to 14, the impression of these preventive measures has not been very notice-

TABLE 5.—PERCENTAGE OF ADMISSIONS FOR RHEUMATIC FEVER

	Winter	Spring	Summer	Autumn
	Dec., Jan., Feb.	Mar., Apr., May	June, July, Aug.	Sept., Oct., Nov.
1915 (+ Dec., 1914).....	18.3	39.6	29.1	12.8
1916.....	19.5	46.1	28.7	5.6
1917.....	14.9	45.6	32.4	6.6
1918.....	30.6	40.9	23.7	4.7

able. In young adults from 15 to 29 there has been a strong impression made. Has this been due to disinfecting the teeth or removing tonsils or both, or neither? From 30 years to 50 there has also been evident results of dental work. To confirm these impressions, 1,000 consecutive histories of rheumatism were examined in Bellevue in the 1915-1918 period. In the

forty-three children of this group, 58 per cent. are recorded as having bad tonsils and 53.4 per cent. as having bad teeth. The records show that 25.3 per cent. of these 1,000 patients had tonsils noted as bad and 68.3 per cent. had teeth noted as bad. Thirteen per cent. are noted as having both tonsils and teeth bad. Tonsils alone seemed to be the focus of infection in 11.3 per cent., teeth alone in 55 per cent., and both bad in 13 per cent. The teeth are mentioned as good in only 6.7 per cent. of these 1,000 patients, and thirty-one of these sixty-seven patients are noted as having severe tonsillar infections.

As a possible checking comparison, the records of 250 consecutive cases of pneumonia were studied to see in what proportion the teeth and tonsils showed infection but with no rheumatism or other arthritis. The percentage of bad teeth in this group is 57, as against 68 of the rheumatic group, and the total percentage of tonsils noted as bad, 17 as against 25.3. More striking, however, is the percentage of patients in whom the teeth are noted as good, being 19, as against 6.7 in the rheumatic cases.

It is impossible to state what percentage of these cases showed cardiac involvement. In 1908, in studying the histories of 500 cases of rheumatism in Bellevue, 253, or 56.6 per cent., showed recent or old endocarditis. If the cardiac involvement dominated the clinical picture, the patient would probably be recorded under acute or chronic cardiovalvular disease and not under acute rheumatism. The liability, moreover, to cardiac involvement varies with age, the figures of Church showing 75 per cent. for children under 10 years of age and liability to their involvement diminishing, until over 40 years of age the percentage was 12.5 per cent.

* Cases excluded history showed patient suffering from some other disease.

† Of these sixty-seven cases, thirty-one are especially noted as instances of marked tonsillar trouble.

CONCLUSION

These figures were obtained in gathering material for a report on health insurance to see whether or not there had been an actual diminution in the number of cases of acute rheumatic fever admitted to Bellevue Hospital, and to see whether any deductions could be drawn from them regarding the wisdom of including dental hygiene in the preventive measures of social insurance. They are too limited for any sweeping generalizations. But it would seem that the actual and striking diminution of total admissions for rheumatic fever of the past two years was more than accidental, and that for this the dental hygiene more than any other one factor was responsible. That tonsillectomy has also made its impression is most probable, as the diminution of both total number of admissions in the

20 to 29 year group and the percentage ratio to total number of this group is really most striking, especially since during this period of life the liability to rheumatic infection is especially noticeable. The average number admitted of 20 to 29 years of age during the four year period 1911 to 1914 was 180, while during the five year period 1915 to 1919 it was 110. The ratio to total admissions has also fallen from 17.8 per cent. for 1911 to 1914 to 15.3 per cent. for 1915 to 1919. The two periods from 20 to 29 are the periods in which the figures show most definitely an average reduction of percentage to total, combined with a definite reduction of total admissions. Have tonsillectomies begun to tell, or has it been oral and dental hygiene? Undoubtedly both, as ten years have not elapsed since tonsillectomy before 15 years of age has become widespread, so that it could not previously have affected the older years of this and other age groups in the community.

ADEQUATE PREPARATION FOR THE PRACTICE OF OTOLARYNGOLOGY

DISCUSSION OF AN OLD PROBLEM*

GEORGE E. SHAMBAUGH, M.D.

CHICAGO

As an introduction to my discussion I wish to relate a few experiences which have come to me recently.

REPORT OF CASES

CASE 1.—Last December a man, aged 23, consulted me about his ear trouble. He stated that for perhaps six or eight years he had noticed an insidious development of deafness, associated with a persistent tinnitus aurium. At first only one ear was involved, but for two years both had been affected.

Both drum membranes were unusually transparent, but in other respects they were quite normal. The functional tests revealed a marked elevation of the lower tone limit, a strongly negative Rinne test for both ears, and an actual prolongation of bone conduction, with an extensive defect at the upper tone limit. The diagnosis was clearly one of otosclerosis, producing fixation of the stapes and a degeneration in the labyrinth. The lower and middle turbinated bodies had been removed from both sides, the septum had been resected, the faucial tonsils had been enucleated, and the nasopharynx had been curetted. In the operation on the faucial tonsils, both posterior pillars had been removed. The result of these operations was a marked pharyngitis sicca, with crusting in the nasopharynx, thickening of the lateral bands of the pharynx, caused by the removal of the posterior pillars, and an annoying rhinitis.

The patient stated positively that he had never experienced any nose or throat symptoms prior to his operations, and that the series of operations had been performed to arrest his increasing deafness. It is at once apparent to any one who understands the diagnosis of ear diseases that this patient was suffering from a form of ear trouble which has no especial relation to nose and throat conditions, and that operations on the nose and throat could not be expected to better his ear condition.

CASE 2.—Last month a man, aged 20, was referred to me from a neighboring state because of tinnitus aurium, which had annoyed him for more than a year. A letter from his family physician stated that the patient was coming to me to have carried out a series of operations on the nose and throat, which had been recommended by a local specialist, in order to save the patient from losing his hearing. The

* Read before the Chicago Laryngological and Otological Society, March 1, 1920.

operations that were recommended included resection of the nasal septum, turbinectomies and removal of the tonsils. The patient was experiencing no nose or throat trouble. Both drum membranes were quite normal, and the functional examination disclosed no defect in the hearing. It was possible that the tinnitus was being caused by an incipient otosclerosis, which had not as yet produced any defect in the hearing. One thing was certain: the patient did not suffer from any middle ear disease which could have been influenced by nose or throat conditions.

CASE 3.—During the same week a young woman residing some distance from Chicago consulted me about having a mastoid operation, which she had been urged to have done. The hearing in the right ear was very much reduced, as the result of an exhausted suppurative otitis media. The hearing in the left ear was only slightly impaired. In this ear there was found a slight mucous discharge which came from a large perforation in the anterior segment of the membrana tympani. This discharge, the patient stated, had recurred from time to time in this ear since childhood. There was no odor. It was because of this discharge that the radical mastoid operation had been urged as a prophylactic measure to prevent a possible serious intracranial complication. The palpable facts in this case were, first, that the patient was not suffering from a form of ear trouble which leads to a serious complication and, second, that an operation had been proposed which might very easily result in a serious impairment of the hearing in the one ear on which the patient had to rely. In other words, an operation was proposed for an ear condition which did not require an operation and, furthermore, if a condition had really existed in this ear which would ordinarily justify an operation, such a procedure would be warranted in this case only in the presence of symptoms indicating an impending serious complication, because it was the one ear on which the patient had to rely for hearing.

CASE 4.—A few weeks ago a patient came to the Presbyterian Hospital suffering from a discharging ear, the result of an acute otitis media. He stated that his ear discharge had begun last December and that practically from the onset he had suffered from pain, more or less severe, in the mastoid, and that the region over the process had been swollen and tender for a couple of weeks. Only two days before I saw this patient he had been urged to have his tonsils removed, a submucous resection of the septum performed, and turbinectomies, in order to cure his discharging ear.

COMMENT

Here is a series of cases presenting the most elementary clinical problems that confront the otolaryngologist and in each instance entirely wrong advice has been given. The questions arise: What is the cause of this state of affairs, and is there a remedy? The cause for this condition is the fact that the country is literally flooded with general practitioners who have found a lucrative field of work in doing operations on the nose and throat, but who have had no fundamental training in otolaryngology which has prepared them to make the proper examination or to diagnose the conditions requiring these operations. For years general practitioners have been coming to our city clinics, especially to the so-called postgraduate schools, with the sole object of learning the technic of a few operations on the nose and throat. It has been proverbial that these men have not been interested in learning the principles of otolaryngology. Diagnosis has not especially interested them. They came to get a smattering of technic for a few operations. This they could get in a few weeks, whereupon they returned to their practice to begin doing these operations on their patients. It is not surprising that the wrong advice is so frequently given, or that so many unnecessary operations are being performed.

The remedy for this state of affairs is equally clear. The representative otolaryngologists throughout the country should insist that the practitioners who come to them for instruction should first acquire a knowledge of otolaryngology before they are taught to do operations in this specialty. Otolaryngology is not such a difficult subject that it requires a genius to master its principles. On the other hand, it is just as clear that these principles cannot be acquired by a few weeks or a few months' attendance at postgraduate clinics. We should insist that a physician who is preparing to practice otolaryngology should spend as a minimum one year of full time work in the study of this subject. His work during this year should be as much in the study of the fundamental sciences of anatomy, embryology, physiology and pathology as in the study of the clinical aspects of the subject. It does not suffice that he assist in a clinic during this year, where the chief work is the removal of tonsils and the correction of septum irregularities. His reading should be directed, and assistance should be given him in learning to make diagnoses and to understand the proper indications for operative treatment. The technic of operations should be taught only as the final part of such preparation. It is a relatively simple matter to teach a student the technic of operations. It is a difficult problem to teach the methods of examination and the making of diagnoses. The situation throughout the country does not call so much for a large number of men to do the work in otolaryngology as it does for the adequate training of only a relatively small fraction of the men who are at present attempting to take care of this work. I am told that in many communities the number of men who are limiting their practice to otolaryngology often exceeds that of the men doing all the other medical work, and that these men are succeeding financially more than their fellows largely because of the unnecessary surgical work which they are undertaking to do.

We owe it to the public and the specialty which we are attempting to represent that we take a definite stand on this proposition of adequate preparation for practice in this field. We cannot directly control the unscrupulous practitioner who takes a case in which we refuse to operate and which he himself knows does not require an operation, and who subjects the patient to, say, a tonsil enucleation, simply because the patient has got it into his head that his tonsils are causing an imaginary trouble; but we can and should control the preparation of men who are attempting the operations in our specialty without knowing the indications for these operations. The need of controlling the preparation for special practice is much greater now than it was a few years ago, when the general practitioner was attempting to treat these cases simply by using sprays and topical applications. No special harm to patients was done by such treatment. But give these practitioners enough knowledge of the technic of an operation or two on the nose or throat, so that they can undertake to do these operations, and the field for harm by doing unnecessary surgery is opened.

This is not a new problem. In 1907 I insisted¹ that the preparation for special practice should be as much in the fundamental sciences as in the clinical study. I emphasized the point that this work should be done in the laboratories of the university, and was the first,

1. Shambaugh, G. E.: The Preparation of the Specialist, J. A. M. A. 49: 540-543 (Aug. 17) 1907.

I believe, to express the view that it be put on the basis of genuine graduate work leading to the granting by the university of a higher degree, the degree of Doctor of Philosophy, for example, in Otolaryngology. We now for the first time see this proposition being taken up by some of our universities.

Again in 1909 I pointed out² the inability of the existing postgraduate schools to provide more than a smattering of clinical instruction, which, after all, is of minor importance in the proper training of the real specialist as compared with the benefit derived from adequate instruction in the fundamental sciences, which can be acquired only in the laboratories of a university.

Finally, in 1912, I emphasized³ the fact that the real specialist in medicine, just as in any field, is the man who by perseverance and concentration of effort succeeds in placing himself in touch with the advanced line of work, where he is able to see and to attack the various unsolved problems in his particular field: that the specialties are no place for the dilettant in medicine or for the unsuccessful general practitioner. I pointed out the analogy between the work of the postgraduate schools in training specialists and that of the existing proprietary medical schools in training general practitioners, and insisted that the proper place for both of these fields of instruction was in a properly equipped department of medicine of a university.

Since these articles were written, we have seen the passing of the proprietary medical school and the taking over of undergraduate medical instruction by the university, where it rightfully belonged. I believe that we are now about to see the passing of the postgraduate school as an institution for training men practicing the medical specialties. Already the universities are reaching out into this field, and it should not be long before we shall see the preparation for the medical specialties put on the basis of real graduate instruction in the university department of medicine. When this is accomplished there will be less effort made to ladle out to these students medical facts in courses devised for this purpose. The aim will be rather to lead the student to acquire knowledge of facts by his own observation and by reading. Courses of instruction aiming to drill the student in the established facts in medicine are always superficial. It is not so much the number of facts that the physician is able to acquire in his preparation as a specialist that matters. It is rather the training to investigate these facts that is of greatest value. It is right here that postgraduate instruction in this country and abroad has failed signally in the preparation for special practice. Physicians who have relied on the taking of such courses for their preparation have too often completed this instruction with the belief that they have acquired a knowledge of the important things in otolaryngology, whereas they have missed entirely the most important element in the proper training of the specialist, namely, the training, and the desire inspired by the training, for investigating these facts. Few of all the men who in the past have filled our postgraduate medical schools and have crowded the courses offered for specialists abroad have ever become contributors to the advancement of our specialty.

A COMPARISON OF METHODS FOR DETERMINING THYROTOXICOSIS*

MALCOLM S. WOODBURY, M.D.

CLIFTON SPRINGS, N. Y.

The observations which form the basis of this paper were made during the last eight months, beginning July 1, 1919, and were prompted by a desire to compare, particularly, the epinephrin chlorid test, as described by Goetsch, with basal metabolism determinations, as advocated by Benedict, Du Bois and others, in relation to certain clinical and pathologic observations.

The questions which presented themselves were: (1) the clinical condition of the patient, as determined by a standard, carefully planned method of history taking and examination; (2) the response to the epinephrin chlorid test; (3) the basal metabolic rate as determined by oxygen consumption; (4) the pathology of the thyroid after operative removal, and (5) the clinical result of operation.

For purposes of accumulating clinical data, a special thyroid sheet was utilized. The epinephrin chlorid test as described by Goetsch was applied as we have been accustomed to apply it for the last three years. The basal metabolism was determined by utilizing the Benedict portable apparatus, the precautions advocated by Benedict and Carpenter being strictly observed. Only oxygen determinations were made in most instances. Dr. C. W. Webb operated on those patients that required operation. The pathologic examinations were made by Dr. W. S. Thomas.

The probable hyperthyroid cases coming under observation between July 1, 1919, and Jan. 1, 1920, numbered fifty. Among these were twenty-nine patients for whom operative treatment was thought to be indicated. The other twenty-one composed a group made up of patients for whom measures other than operative were employed. There were no very active cases in this group, and they will receive no further consideration at this time. From the clinical point of view the operative group comprised two main types: first, the severely toxic cases; all, on whom it was thought safe to try the test, showing markedly positive epinephrin chlorid reactions, and increased metabolic rate, varying from 20 per cent. to 85 per cent., and clinical evidences too obvious to be by any possibility mistaken; and second, a type showing symptoms milder in degree and without exophthalmos. The second type responded positively to the epinephrin chlorid test in varying degrees, but showed a metabolic rate which was low, or not increased above the limits now accepted as normal.

The last statement will bear reiteration, for on it the reason for the presentation of this report rests. We encountered patients with varying degrees of thyroid enlargement, who were incapacitated for ordinary activities over periods of very considerable duration, whose symptoms suggested thyrotoxicosis, who gave a positive response to the epinephrin chlorid test, but who had normal metabolic rates. The problem was this: Would operation in such cases be justifiable? Basing our decision on a rather large number of past observations on patients who seemed to be similar in type, but who had been examined before we were able to determine the metabolic rate, and who had shown

* Read before the Buffalo Academy of Medicine, Jan. 14, 1920.

very satisfactory postoperative results, we advised operation in certain of these cases.

Considering, on the one hand, the excellent work of Du Bois and others on metabolism in hyperthyroidism, and, on the other hand, the now popular acceptance of an increase in metabolic rate as determinable by the ordinary methods as the *sine qua non* of toxic thyroid states, and especially considering its apparent acceptance by the U. S. Army as a criterion, it seems a matter of importance to attempt to discover whether or not so general a conclusion is in fact fully justified. Leaving aside the question of specificity of functional tests, there is a rather general agreement that toxic thyroid states when marked in degree produce quite definite clinical pictures and give definite and constant responses to estimations of metabolic rate, and, in most instances also to the epinephrin chlorid test. But it is not at all generally conceded that there is a rather large group of patients who are in a definitely impaired physical and nervous condition, who, because of a toxic state, of probable thyroid origin, are in need of positive medical or surgical aid, and yet whose metabolic rate is not increased.

Among the thyroid patients that were observed in the period stated and that came to operation, there were five active exophthalmic cases—one carcinoma of the thyroid; one chronic thyroiditis; and three markedly toxic adenomas; the remaining nineteen patients, not exophthalmic, on whom operation was performed, were thought to be showing varying degrees of toxicity, but did not show increase in metabolic rate. From this point our discussion is limited to these nineteen.

CLASSIFICATION OF CASES

Prior to discussing with Dr. Thomas the pathologic picture in these cases, I arranged them clinically in two subgroups: the first containing the patients who were thought likely to show fairly positive pathologic evidence of overactivity; the second, those that seemed less toxic. After pathologic examination, one case thought clinically to be moderately active, failed to show on section much corroborative evidence, and two of the less active cases showed evidence on section which quite paralleled the evidence in some of the cases that were clinically more active. Possible ground for errors in classifying these three cases may be found in the fact that the patient who was thought to show clinically moderately active thyroid disturbance, associated with tremor and cardiovascular irritability with intermittent palpitation and tachycardia, was a young, rather frail woman, weighing only 80 pounds, and having a moderate sized goiter which showed on section simple, diffuse hypertrophy. In this case overabundance of not especially overactive thyroid tissue may, in so frail a subject, have produced symptoms out of proportion to the apparent pathologic condition. Of the other two patients whose glands appeared on section rather more active than the clinical picture would indicate; one was a farmer's wife, weighing 209 pounds, whose history indicated rather short duration of the thyrotoxicosis; the other was a young woman who had been leading a life of quiet invalidism for three years, a state which, in the absence of thyroid crises, may have tended to a reduction of her symptoms. These three patients showed definite postoperative improvement. Of the other five patients belonging to the second subgroup, that is, the clinically least active cases in which operation was performed, four,

on section, presented the appearance of simple diffuse hypertrophy, and one that of colloid goiter.

The eleven remaining cases of the nineteen under discussion constitute a subgroup of special interest, in that they appeared to be definitely thyrotoxic, gave positive response to the epinephrin chlorid test, showed basal metabolism rates within normal limits, were with one exception very definitely benefited by operation, and showed on section glands that were thought to be compatible with the theory of thyrotoxicosis. The histopathology of the thyroid has not reached a state of much certainty, but the glands represented in these eleven cases probably all belong under one or another of the types of adenomas as described by Goetsch, Simpson and others.

We are not now concerned with the selection of types of therapy, but have chosen to refer only to patients that came to operation because this is the only class of patients available for combined observations of the type under consideration.

FACTORS OF ETIOLOGIC SIGNIFICANCE

To refer in a little more detail to the eleven cases which constitute the subgroup on which our conclusions actually rest, factors which may have had some direct or indirect etiologic significance were: family history, 8; nervous strain, 4; nervous shock, 0; infection, 9; adolescence, 3; pregnancy, 4. Most of these patients were from western New York, Ohio and Pennsylvania.

The symptoms were thus distributed: nervousness, 11 (nervous hypertension, 6; depression with nervous hypertension, 5); tremor, 6; dyspnea, or dyspnea on slight exertion, 5; palpitation, 10; tachycardia, 9; loss of strength, 9; vomiting, 0; diarrhea, 0; insomnia, 5; free perspiration, 6; edema (feet and ankles), 3; headache, 8; vertigo, 5; generally increased pigmentation of the skin, especially of the forearms, 1; weight loss (moderate), 5; exophthalmos, 0; eye grounds negative, 11; vocal cords negative, 11; tonsils infected, 9; periodontal infection, 3; goiter, 10; definite nodules felt in 4. The known onset varied from a few months to twenty years. The goiter had recently increased in size in 8; there was no dysphagia; slight pressure symptoms were noted in 3; no organic heart lesion was discovered in any case.

The epinephrin chlorid test was clear, positive and of moderate degree in 6 cases; clear, positive and of more marked degree in 5. Basal metabolism results in the eleven cases were: 11 per cent., high; 6 per cent., low; 5 per cent., high; 8 per cent., high; 8 per cent., high; 20 per cent., low; $4\frac{1}{2}$ per cent., low; 14 per cent., low; 2 per cent., high; 7 per cent., high and one, flat normal. Readings not varying more than 15 per cent. from the normal are regarded as normal.

On section, the eleven thyroids all showed definite abnormalities of a type suggesting functional overactivity.

I realize that I am treading on somewhat treacherous ground in making this statement in view of the present uncertain state of knowledge of thyroid histopathology. The pathologist cannot be expected to draw clinical deductions. It seems fair, however, to assume, in case one finds in a glandular organ, such as the thyroid, increase in the height and size of active cells and in cellular elements, with infolding of the walls of the acini and a decrease in colloid, provided these changes are sufficiently clear to any intelligent observer and sufficiently abundant, that the tissue in question is probably more active than is the case in normal tissue

A further index, according to Cowdry, Goetsch and others, is furnished by the abundance of mitochondria in the cytoplasm of the functioning cells, mitochondria being small granular and rodlike bodies of characteristic staining reaction which are far more abundant in cells that give evidence of a high degree of activity of growth or function than in cells of low activity.

In the pathologic study of the group of eleven cases under discussion, the histologic picture of the type just mentioned was clearly present in all, though varying somewhat in degree.

As to clinical results following operation, I have reports from all eleven cases, and despite the fact that these patients were recently operated on, the longest interval since operation being eight months, and the shortest about six weeks, the reports, with one exception, are excellent. In this one instance, a recent case, there seems to be no marked improvement. This patient was sent to Dr. Webb for thyroid operation after six months' rest at Saranac. Her symptoms were marked nervous tension, sleeplessness and fatigue, with pronounced palpitation. The epinephrin chlorid test was made by Heise at Saranac and reported moderately positive; the gland, on section, showed definite hyperplasia with cells generally of high columnar type. This patient is of a definite psychasthenic type, and the present conditions of her life do not conduce at all to a good outcome. The other ten report progress of very positive character; the generally enthusiastic tone of the reports is noticeable. The symptoms specifically reported as relieved are: nervousness in 10; tremor in 4; palpitation in 10; strength loss in 4; headache in 5; insomnia in 5; excessive perspiration in 4; vertigo in 1, and weight loss in 4. Our letters of inquiry were general rather than in the form of a questionnaire, which would doubtless have brought more detailed information.

There can be no doubt, since the thorough work of Benedict and Carpenter, that the Benedict portable apparatus, when used with due regard for the various possibilities of error, furnishes an entirely satisfactory means for the measurement of oxygen consumption. Nothing occurred in the observations under discussion to raise a reasonable doubt as to the accuracy of the observations.

THE EPINEPHRIN CHLORID TEST

The epinephrin chlorid test is rather generally conceded to be an indicator of hypersensitiveness of the sympathetic system, rather than to furnish specifically a measure of thyroid activity per se. On the other hand, it appears to be a fact that positive responses to this test are far more common in cases in which there is thyrotoxicosis than in other instances.

The injection of epinephrin chlorid solution in sufficient dose has been definitely shown to speed up metabolism, increase blood sugar, and produce slight evidence of acidosis, as is indicated in slight increase in acetone bodies in the blood and slight decrease of carbon dioxid combining power in the blood. Without quoting the detailed figures and remarks which appear in each test, it is a little difficult to classify the results of the Goetsch test clearly. No test is regarded as even mildly positive in which a rise of at least 10 points in pulse and in systolic pressure does not occur after the injection of 0.5 c.c. of 1 to 1,000 epinephrin chlorid solution, nor is a test regarded as positive unless there are clear cut subjective symptoms and tremor. With those requirements as the minimum, one may interpret approxi-

mately the terms moderately or markedly positive. The test is beyond question very striking in many instances and should be applied in all doubtful cases, not because it furnishes a criterion, but because it tends to stimulate closer study, and to offer aid in formulating a diagnosis.

In excitable persons we are accustomed to check up the test with injections of sterile water. Unfortunately, the personality of the examiner also needs consideration. Furthermore, observation of the rate of basal metabolism alone, as now estimated, should not be regarded as a sufficient criterion in determining the presence or absence of toxic states associated with the thyroid. The evidence thus obtained is of much value in estimating varying degrees of toxicity, but should receive only its proper emphasis, the complete study of the patient furnishing the only safe guide.

The epinephrin chlorid test is more sensitive and requires even greater safeguards than the estimation of oxygen consumption in many instances, and while one must not be misled to believe that no degree of thyrotoxicosis can be present unless there is increased metabolic rate, one must beware of accepting the belief that every patient responding positively to the epinephrin chlorid test requires radical thyroid treatment. No functional test yet described is pathognomonic.

Important as is the function of the thyroid in the regulation of metabolism, other factors must be taken into consideration before the picture can be regarded as complete.

SUMMARY

Observation of a selected group of eleven patients appears to present sufficient evidence to warrant the diagnosis of thyrotoxicosis, as determined by clinical observation, pathologic study of the portions of the thyroids removed at operation, and postoperative progress. These patients before operation but after rest responded positively to the epinephrin chlorid test and negatively to estimations of basal metabolic rate. They were all of the nonexophthalmic (adenomatous) type; more toxic cases of the exophthalmic and adenomatous types observed during the same period showed increased metabolic rates ranging from 20 per cent. to 85 per cent. above the normal base line.

CONCLUSION

Complete methods of examination with special attention to the possibility of errors in case of psychoneurotic patients should furnish the basis for diagnosis, rather than reliance on any functional test, though the functional tests are of great value in the compilation of evidence, especially in relation to the degree of toxicity.

The Needs of the Children of Porto Rico and the Virgin Islands.—In his seventh annual report, the chief of the children's bureau, U. S. Department of Labor, urges that the needs of the children of our island possessions, be made a subject for official investigation. In Porto Rico, there are "about 10,000 homeless children under 12 years of age, who live by whatever means they are able, many of them begging or stealing, and most of them having no permanent lodging place, sleeping at night in boxes or on doorsteps, or wherever they happen to find a lodging place secure from the rain. These children are, for the most part, deserted and abandoned children of illegitimate parentage, or orphan children whose parents have left no provision for their care and education, and they constitute a fertile soil for the implanting of criminal tendencies and are ready material for older people of criminal habits."

POISONING BY ALCOHOL "DENATURED"
WITH NITROBENZENE*

R. W. SCOTT, M.D.

AND

P. J. HANZLIK, M.D.

CLEVELAND

During the last Christmas holiday season a large number of dark, ghastly looking patients who had been drinking "denatured alcohol" were brought into the City Hospital within a few days. As a rule they were unconscious. The dark, almost black, discoloration was limited mainly to the extremities, face and neck, including a fringe of the upper portion of the chest. In other words, the richly vascular, pigmented and dependent portions of the body were principally involved. The color was not the typical blue of ordinary cyanosis, but rather a livid, brown-black or nearly black, suggesting the presence of methemoglobin in the blood. Except for the deep narcosis and a moderately rapid pulse, the patients were otherwise practically normal. No other circulatory and no respiratory disturbances were detectable. After a deep sleep of about twenty-four hours, the patients left the hospital fully recovered. They did not seem to suffer, and there were no fatalities.

OBSERVATIONS

Blood.—This appeared rather chocolate colored. Spectroscopic examination revealed the presence of two typical bands of oxyhemoglobin, and a single band in the red. On reduction by ammonium sulphid, these were replaced by the broad band of reduced hemoglobin, the band in the red portion of the spectrum disappeared, indicating the presence of methemoglobin.

Analysis of the "Alcohol."—A pint of the beverage ingested by the patients was analyzed. Qualitatively, the presence of ethyl alcohol was established by the dichromate-sulphuric acid test and the refractometer. Methyl alcohol was absent, as indicated by the refractometer. Quantitative estimation of formaldehyd was made by the phloroglucin reagent¹ after oxidation with a copper spiral. Free formaldehyd was present in the alcohol to the extent of about 1:500,000, according to the phloroglucin test. Strong positive tests for nitrobenzene were obtained by means of the zinc dust-acetic acid hypochlorite test, and also the indophenol reaction. The odor of nitrobenzene was distinct, resembling the odor of common shoe dyes. Quantitatively, ethyl alcohol was present to the extent of 61 per cent. (by refractometer). For these refractometer estimations we are indebted to Mr. Percy Tarver of the City Health Laboratory.

COMMENT

The results of our examination indicate that the peculiar dark (black) discoloration in these patients was due to methemoglobinemia arising from the ingestion of nitrobenzene in the "denatured" alcohol. The narcosis was, of course, due to alcohol. The relatively low concentration of formaldehyd found is negligible so far as toxicity is concerned.

The symptoms observed are practically the same as those described by Stifel² in soldiers who were

poisoned by the use of a shoe dye containing nitrobenzene. As reported by Stifel, recovery from nitrobenzene poisoning is prompt and spontaneous. In other words, this "denaturizing" agent is relatively harmless. The beverage so denatured is not rendered altogether unpleasant, either. However, denaturization by nitrobenzene is illegitimate, the law requiring either of the following with certain concentration limits; mercuric chlorid, hydrochloric acid, formaldehyd, phenol and tannic acid, alum, formaldehyd and camphor, and liquor cresolis compositus.

Chronic poisoning from the prolonged use of alcohol containing nitrobenzene might be different from the acute poisoning here reported. Tolerance even to small doses of nitrobenzene is not known to exist, and if it is possible, the cyanosis and methemoglobinemia might still exist, though probably of low grade. Digestive disturbances, visceral degenerations, etc., arising therefrom are conceivable. These might confuse the diagnosis of minor maladies. Physicians, therefore, should bear in mind the rôle of uncommon and relatively harmless, though active poisons, which may be added to or used in alcoholic beverages for deceptive purposes.

SUMMARY AND CONCLUSION

Acute poisoning by alcohol "denatured" with nitrobenzene, and containing a low concentration of formaldehyd, occurred in a number of cases. Although apparently low grade and nonfatal, there is considerable potential harm from such beverages when used over long periods, confusing at the same time the diagnosis of minor maladies.

FITS AND FALLACIES

RUSSELL G. MacROBERT, M.B. (Tor.)

Associate Physician, Neurological Institute

NEW YORK

In the recent mobilization of the American Army, the number of rejections solely for nervous and mental disease rose early in places to 5 per cent. of the total number. Of the first 13,481 of such rejections, 12.8 per cent. were for epilepsy. A simple calculation based on these figures puts the incidence of epilepsy among the young men examined at one in 150. Such incidence seems an exaggeration of the frequency of epilepsy in our population, but most similar rough indications point to a frequency sufficient to establish a more pressing claim on general medical attention.

Certainly great numbers of epileptics come to the Neurological Institute from far and near. Three hundred and eighty-eight new patients were added to our lists last year. There is a great variety of conceptions among them regarding their ailment, many of which are quite ridiculous. These conceptions correspond in some measure to past treatment, which varies all the way from the merely futile and ineffective, to the positively harmful and dangerous. Epileptics are dieted, purged, disinfected, analyzed, circumcised and sterilized; women are deprived of their pelvic apparatus; bowels are taken away, heads broken into—every conceivable sort of activity is being indulged in and advocated for the cure of epilepsy.

This does not so much impute discredit to the physician in charge, whose attitude toward these patients is practically always one of sympathy and

* From the Medical Clinic, City Hospital and the Pharmacological Laboratory, Western Reserve University School of Medicine.

sincere well meaning, as it does reflect the confusion of ideas on the subject with which the medical press of the day abounds. Every one writes about epilepsy, and each explains it according to his light; and as it is possible for a man to be wrong in his main argument and yet deliver fifty truths in arriving at a false conclusion, unsound reasoning and invalid argumentation accordingly spread apace. So today there is a veritable chaos of conflicting views regarding the cause and treatment of epilepsy, but it can be easily shown that a fallacy forms the basis for most of the unique current cures.

This paper is an attempt, by a brief consideration of some of the more popular misconceptions, to clear up somewhat the confusion concerning the very interesting but much abused problem of convulsions which must surround the general practitioner under whose care most epileptics are, excepting those in the big cities.

HEAD SURGERY

Whether from a real belief in the efficacy of the procedure, or whether merely from a feeling of helplessness combined with a desire to try something, there

has been in the past much ill-advised and indiscriminate surgery performed on the heads of epileptics. Such operations are performed chiefly in an effort to remove a source of irritation. This implies a likelihood of finding in epileptics some gross lesion, and a possibility of eradicating it when found. A consideration of the character and frequency of gross brain lesions found in the brains of epileptics is pertinent.

In 845 necropsies at Craig Colony on the brains of epileptics, gross lesions are reported present in 60 per cent. In the 205 necropsies at the Monson State Hospital for epileptics, the percentage is almost the same—61.5 per cent.

To indicate the character of the lesions encountered, and included in these percentages, a list of the 1919 series of necropsies at Craig Colony is shown in the accompanying tabulation. It is a fact worth remarking that forty out of every 100 epileptics show no gross deviation from the normal even when gone over in the comprehensive manner that the table indicates. However, to accept even these figures as an indication of the prevalence of gross brain lesions among the great mass of sane and unconfined epileptics is for several reasons a great error.

In institutions of this kind, the disorder is seen in its severest form and in the worst type of individual. For instance, 128,725 convulsions were reported to have occurred at Craig Colony among the 1,700 epileptics treated there in the year ending June 30, 1917. This indicates for each patient an average of seventy-five. The records of the Monson State Hospital for Epileptics show that 90 per cent. of the necropsies were on the victims of mental disorder. In fact, all but one of the brains in their series of 116 reported abnormal were from patients that were feeble-minded or demented.

Of course, these institutions do not assert that these gross lesions are the cause of the disorder. As to their significance, the statement is made, in a study of this point from the Monson State Hospital, that, "like the manifestations of the disease itself, the lesions are often of a spectacular character, yet it is most difficult to state whether these lesions are the cause or the effect of the convulsions, or whether they are in any way correlatable with epilepsy."

In this connection it might also be added, regarding the significance of gross brain lesions to the cause of epilepsy, that, in the recent review of a large series of brain tumor cases at the Neurological Institute, fifty-two out of fifty-three never exhibited generalized epileptiform convulsions at any time during the course of the disease.

However, without further discussion as to whether the lesions tabulated bear any causative significance so far as the occurrence of convulsions is concerned, let us view the list of lesions included here, merely from the standpoint of a surgeon hoping to cure epilepsy by operating on the head. It is apparent immediately why observers at Craig Colony, despite the great number of gross lesions that they have enumerated, have been impressed by the fact that it is rare to find at necropsy a lesion which might have been benefited by operation during life. Not only this, but necropsies there on patients operated on during life showed almost constantly postoperative adhesions of the meninges to bone or cortex. Surgeons who propose operating on the heads of epileptics might do well to read Munson's¹ paper on this point.

The fallacy of operating on the heads of epileptics, therefore, in an effort to find and remove some suspected focus of irritation, is demonstrated by these few points concerning gross brain lesions, which may be thus summarized: 1. It is an error to assume that gross brain lesions exist in or about the brain in the average unconfined epileptic in any percentage of cases approximating that given out by institutions for the epileptic, such as Craig Colony and the Monson State Hospital. 2. It is not proved or even intimated that the gross brain lesions enumerated in the statistics of these institutions are primary causes of the disorder. 3. The character of the gross brain lesions described precludes practically always the possibility of successful operative interference. 4. Necropsies on patients operated on showed almost constantly postoperative adhesions. 5. The results of operation, to say the least, are unsatisfactory.

BRAIN TUMOR

Some operations are undertaken, too, on epileptics in the belief that a series of abortive or localized

1. Munson, J. F.: End-Results of Head Surgery in Epilepsy, New York State J. M. 12: 638, 1912.

attacks must surely be caused by a tumor or other gross disease of the motor cortex. Apropos of this point there are two facts concerning epilepsy which, if more generally appreciated, would save many epileptics from a useless operation on the head: 1. The incomplete or abortive seizures which occur irregularly in the intervals between the major attacks of epilepsy are the complete seizures reduced to their initial symptoms. 2. However diversified these attacks may be, they are always or nearly always similar in the same subject.

Repeated incomplete convulsions, therefore, since they always affect the same limb, appear almost compellingly suggestive of circumscribed disease of the motor cortex in the area which represents this limb. This is especially true when paralysis supervenes from temporary exhaustion of the cortical elements by frequent attacks.

A patient presenting these conditions came to the Neurological Institute, Oct. 1, 1919. The localized attacks were so frequent and severe that a motor paralysis of the right hand and forearm occurred, accompanied by a complete loss of joint sensation at the wrist and at all joints below. Although he did not have general signs of brain tumor, he had been in imminent danger of operation on account of the persuasive evidence of the paralysis. Simple sedative treatment was commenced on the day the number of attacks had mounted to fifty-four (his worst day); and it decreased the number of convulsions at once. A week later they were arrested completely. The paralyzed hand then recovered slowly but entirely, so that two weeks after the convulsions had ceased, even the dexterity of the fingers in the formerly paralyzed hand equaled that of the unaffected hand.

This phenomenon occurred in a case of ordinary epilepsy which had got rather out of hand just before coming to the institute. Ten grains of sodium bromid, three times a day, with attention to some other details has completely controlled all attacks to this date.

Localized attacks are not infrequent in the course of ordinary epilepsy. In the absence of the well known signs of brain tumor, a history of having had generalized epileptiform convulsions determines the case to be in all probability one of ordinary epilepsy; for, whereas a generalized epileptiform attack may occur as an early sign of brain tumor, it has been shown recently by the study of a large series of cases at the Neurological Institute that this happens only rarely, once in every fifty-three cases.

It must be remembered that a loss of consciousness may occasionally precede, accompany or follow some one of the strictly one-sided attacks, being caused by a brain tumor in the region of the motor cortex. If the limbs on the other side of the body do not also become convulsed, mere loss of consciousness does not make the attack a *general* convulsion, and it is very important that it be differentiated from one because a localized attack with loss of consciousness has the same significance and localizing value as one in which consciousness is preserved.

HEAD INJURY

There is a more or less prevalent opinion that epilepsy is one of the likely outcomes of injury to the head. Statistics prove that this has no basis in fact. In the Franco-Prussian War, as a result of 8,985 non-fatal head injuries, only forty-six cases of epilepsy

developed, that is, about one in 200, or perhaps a little more frequently than it occurs in the civil population.

This might be considered a suggestion that generalized epileptiform convulsions will be instituted by head injury only in that individual whose unstable nervous system predisposes him to convulsions. Perhaps such a report would read more significantly if put thus: Of 8,985 persons receiving nonfatal head injuries, forty-six proved to be persons possessing a more or less generalized cortical instability, as a tendency to recurrent convulsions became manifest in them.

THE GASTRO-INTESTINAL TRACT

So much emphasis has been placed on abnormalities of the gastro-intestinal tract, and the relation of the superimposed condition of chronic intestinal stasis to convulsive seizures, that as one writer humorously says, it has almost appeared necessary to assume that every constipated person is a potential epileptic. The fact remains, however, that most constipated persons are not, and the absurdity of such an idea should become manifest on its mere statement.

However, not long ago a theory, with gastro-intestinal abnormalities as its basis, was evolved to explain epilepsy. Elaborate and unique details of the mechanism of a convulsion were described in the light of this theory. The cure advocated was a drastic surgical operation—a removal of the large bowel. As might be expected, very ungratifying results, to say the least, followed in the wake of an all too widespread trial of this treatment. The facts on which the cure was advocated were found later to be incorrect, and the whole explanation tumbled and was withdrawn by its exponent.

However, the end of it is not yet. For some reason the operation continues in sporadic popularity. This is not because anybody now believes in the existence of the particular organism described, pictured and purported to be the germ of epilepsy. It can not be because any one still believes that bands, adhesions, etc., in the bowel, cause absorption of bacteria into the blood stream. The persistence of the treatment probably has no better nor other excuse than that all too common fallacy, the belief that any accompanying physiologic irregularity in an epileptic must surely be the cause of the convulsions. And as there were published, with the series of articles advocating this operation for epileptics, numerous and impressive roentgenograms of the intestine in various states of stasis and abnormality, I think that perhaps a lingering memory of these must be exercising an unconscious influence on the therapeutics of the disorder.

Because it is a highly dangerous procedure and its results so futile, it seems worth while to give a moment's further consideration to the basic premise on which the support of such treatment must necessarily depend.

Are gastro-intestinal abnormalities present in epilepsy? In order to study this question, the Monson State Hospital for Epileptics reviewed the protocols of its 280 necropsies on epileptics. Intestinal adhesions and peritoneal bands were present in 17.8 per cent of the cases. By the same process with 775 necropsies at the Boston City Hospital, 18.3 per cent, a slightly larger percentage, was arrived at for nonepileptics! When each portion of the gastro-intestinal tract was compared separately, this relative sameness was found to apply throughout.

The treatment is a product of fallacious reasoning from erroneous premises, and it becomes obvious that convulsions are no indication for surgical exploits on the bowel. Such cures for epilepsy deserve nothing but the severest condemnation.

THE PSYCHOGENIC THEORY

The psychogenic theory for epilepsy came into being about five years ago when the bubble, as it seems to me, of freudian analysis, on which it was based, was blown to its fullest.

Some diffidence in making a postmortem statement regarding a theory might be expected from one who for a time gave it some credence. But any details concerning it seem unnecessary when it is considered that there must now be few who believe that a convulsion is a direct and purposeful attempt of the mind to supplant the pain of an unpleasant reality, with what pleasure might be anticipated, from a temporary and imaginary resumption of prenatal existence.

There may be, however, many who believe that in a more general way psychic influences, such as fright, grief and worry, are potent causes of epilepsy. Here we must differentiate between a primary direct cause and a mere inciting factor of the first attack in predisposed persons. Gowers, who wrote years ago that "as a direct excitant of the first attack intense sudden alarm takes the first place," also made it clear that he considered such excitant but the spark that lights up the fit phenomenon in a person in whom there already exists a more or less generalized cortical instability. That apart from the view intimated by this statement, mind or emotion even in a more general way as expressed by fright, grief or worry can be ever considered a primary causative factor of epilepsy is put in question by the overwhelming contrary evidence supplied by the late war, which proved a great laboratory for the testing of such ideas as this, for in the war all disturbing psychic influences were present in tremendous force. Epilepsy, however, did not often occur. In fact, it was actually rare at the front in the American Army from which recruiting officers had previously excluded with fair diligence all men having a history of convulsions.

When the great frequency of the war neuroses is thought of, in comparison to the relative infrequency of war-evoked epilepsy, psychic shock and strain pale into insignificance as a cause for convulsions in a normal person.

Psychotherapeutic treatment, no matter of what kind, proves by itself absolutely ineffectual as a cure for epilepsy. Any such plan of treatment, if it at the same time denies the unstable epileptic cortex the benefit that certain remedies have been proved to bestow, is wrong, and in my opinion negligent.

THE PITUITARY GLAND

The pituitary gland possesses a strange proclivity to evoke suspicion toward itself as being the source of uncomprehended ailments. Although already much maligned, this is probably the only reason for its first becoming accused of having to do with epilepsy. Pituitary extract as a remedy for epilepsy seems thus to have originated on a basis of pure empiricism, although a few feeble facts have been marshaled in its support.

Chief of these is that an abnormality in the sella turcica is found by the roentgen ray in an occasional

epileptic. It is hardly necessary to say that misinterpretations and fallacies are responsible for many of the reports of deformed, closed and small sella turcicas.

Then it must be remembered that abnormality in size of the sella turcica by no means implies abnormality in the size of the pituitary gland or abnormality in its functioning.

Could the pituitary gland be proved enlarged or undersized in epileptics there would be more excuse for the effort to link up pituitary dysfunction with the cause of epilepsy. However, statistics show that abnormality in size of the pituitary gland occurs but rarely in an epileptic. In the last two years, 203 brains of epileptics were examined at Craig Colony, and in only five could the pituitary gland be considered either larger or smaller than normal. Then, too, there are certain well marked clinical syndromes which occur in dysfunction and disease of the pituitary gland. Convulsions have never been mentioned as a part of these syndromes. In a recent review of 160 brain tumor cases at the Neurological Institute there were eighteen in which the tumor definitely involved the pituitary gland. In not one of these cases did convulsive phenomena of any kind occur.

Nevertheless, pituitary extract for epilepsy has ardent advocates. Not long ago one of these advocates² presented good evidence of its comparative futility, even in epileptics considered to be showing definite indications of pituitary disorder, although unintentionally, as the paper was written in a laudatory endeavor. The study is based on 200 cases of epilepsy, all but twenty-eight of which are at once excluded as not being suitable for the treatment. Its uselessness is thereby at once exclaimed for 86 per cent. of all epileptics! Pituitary gland was fed to the remainder, and as most of these had been taking bromid previously, "this was allowed to be continued." The cures at the author's own rating are four. For the series this would mean one in fifty; for the selected twenty-eight considered to have pituitary disorder, one in seven. The latter result is about half as good with both bromid and pituitary extract as one would expect to obtain with small doses of bromid alone according to such well known statistical tables as that published by Aldren Turner, whose patients completely cured with small doses of bromid alone were 23.5 per cent., or almost one in four.

And yet such reports as the one considered here, to the mere glance of the hurried reader, often seem impressive, and it is not unlikely that this one alone greatly increased the consumption of pituitary extract.

ALCOHOL

Recently it has been authoritatively stated that alcohol as an etiologic factor in the production of insanity has been overrated. There is no doubt of this being true as regards epilepsy. Of course, pathologic alcoholism in the ancestors of epileptics is common. But, like a history of insanity, it is chiefly important merely as evidence that in these ancestors a neuro-pathic defect existed. That is, alcoholism is a sign of something, but by no means necessarily a cause for anything. When an estimation of the proper relation of alcohol to epilepsy is involved, this difference must be appreciated.

2. Tucker, B. R.: Role of Pituitary Gland in Epilepsy. *Arch. Neurol. & Psychiat.* 2: 192 (Aug.) 1919.

For instance, Dejerine asserts that in France one half of the cases of epilepsy among children are due to alcoholic parents. Now, whereas the defect in the nervous system of the parents is perhaps unquestionably responsible for the defect in the nervous system of the child, an assumption that to the alcohol imbibed by the parents is due the epilepsy in the child is far from justified. Alcohol cannot be considered to father epilepsy merely because a man addicted to alcohol fathers a child addicted to convulsions. Such is very obviously a fallacious deduction. However, it is possible that excessive alcoholism in a pregnant woman may interfere with the proper development of the nervous system of the embryo, and so in some instances epilepsy may seem quite properly attributable to alcohol. But otherwise, alcoholism as a direct primary cause of epilepsy has not been proved. There are many who consider that as such it has been misapprehended. They believe the so-called rum-fits to be indicative merely of a dormant epilepsy. Indeed, when we compare the frequency of acute alcoholism with the infrequency of rum-fits, this view does seem plausible.

A study of the relation of alcohol to convulsions was undertaken at the Monson State Hospital for Epileptics. As a result of this study, the statement was made that "in a perfectly stable and well adjusted nervous system, alcohol per se is not sufficient to produce convulsions."

It is not my intention to underestimate the importance of alcoholism in the parents as an evidence of neuropathic stock, or to underestimate the importance of alcoholic intoxication as an irritant to sensitively balanced nervous systems, or to disregard the effect of alcoholic poisoning on the nervous system of the developing embryo. It is my object merely to call attention to the fallacy of assuming that because an epileptic drinks, or his parents drank, such facts make sufficient evidence for generalizations concerning the cause of epilepsy.

EYESTRAIN

Eyestrain may hardly seem worth mentioning, but it is believed by some to be the cause of epilepsy. Indeed, the epileptic eye has been spoken of.

At the Monson State Hospital for Epileptics, "Eyes are marked by no distinguishing feature." Hodskins and Moore³ obtain no positive findings. In fact, evidence was produced to prove that eyestrain was not of any importance as a primary etiologic factor in epilepsy.

CONCLUSION

Perhaps the best and most practical view for the general practitioner to adopt is that epilepsy means a tendency to recurrent convulsions, that such a tendency implies a more or less generalized cortical instability, and that epilepsy is therefore not properly due to any cause outside the brain.

Then, too, it is not an incurable disorder. In fact, treatment in accord with the view just mentioned has for years proved more or less effectual when well carried out. For instance, William Aldren Turner of the National Hospital for the Paralyzed and Epileptic in London, an indisputably eminent authority on this subject, gave some figures in 1910 which might be considered accurate proof of this. He published statistics

of a large series of cases, many observed for as long as twenty-two years, in which small doses of bromid alone had cured entirely 23.5 per cent., or about one epileptic in every four, and greatly benefited another 50 per cent.

At the Neurological Institute we find that practically all epileptics of the class who live at home and are able to visit the hospital derive great benefit from treatment. A cerebral sedative is used almost always, and this is combined with what other remedies or treatment a study of their physiologic processes and particular difficulties suggests.

20 West Fiftieth Street.

EPIDEMIC INFLUENZA AT THE COOK COUNTY HOSPITAL*

JAMES C. SMALL, M.D.

AND

FRED H. STANGL, M.D.

CHICAGO

True to the history of pandemics of influenza of the nineteenth century prepared by Leichtenstern,¹ the great outbreak of last year has been followed by epidemic outbreaks chiefly in the larger cities. So far as conditions at Cook County Hospital obtain, Chicago was invaded early in January, 1920, and during the five weeks ending February 15, 1,128 patients were admitted to this institution. There were 264 deaths among this number, a mortality of 23.4 per cent., as compared to the rate of 31 per cent. at this hospital in the recent pandemic.

The crest of the epidemic (Chart 1) as indicated by admission to this hospital was reached on January 20, after a duration of about ten days. The secondary rise both in admissions and deaths occurred about January 30. This corresponds to the marked increase in the number of patients admitted with pneumonia.

Because of the rather limited hospital facilities, instructions were issued to the examining physicians to accept for hospital care only those patients that were really ill. With such a rule in effect, the distribution of the first 839 patients as shown by the diagnosis on admission to the ward was: influenza, 503, or 60.7 per cent., of which forty-six, or 9.1 per cent., developed pneumonia during their stay in the hospital; influenzal pneumonia on admission to the hospital, 326, or 39.3 per cent. Of the 326 patients admitted with pneumonia, 205 died, a mortality rate of 62.9 per cent. The patients who developed pneumonia in the hospital include, among others, children, patients in obstetric wards, and patients suffering from chronic diseases. In this group of forty-six cases there were twenty-six deaths, a mortality rate of 47.8 per cent.

The unfavorable effect of pregnancy on the prognosis as noted by observers in previous epidemics is again brought out. Of the forty-eight women admitted to the obstetric ward with influenza, twenty-four died, a mortality rate of 50 per cent.

There were two age periods of greatest number of admissions (Chart 2): one from birth to 10 years, and one between the twentieth and fortieth years.

Of the adult admissions, 59.8 per cent. were males and 40.2 per cent. were females, a relationship prac-

tically identical to the percentages of last year, 59.2 of males and 40.8 of females,² respectively.

CLINICAL PICTURE

The clinical picture was in all essentials like that described during the previous outbreaks of the disease. The onset was abrupt, with the features of acute

Chart 1.—Duration of the epidemic as shown by daily admissions (solid line) and deaths (broken line).

catarrhal fever. The prostration and debility were all out of proportion to the demonstrable pathologic changes. Among the common complaints were coryza, headache, retrobulbar pain, backache, chilly sensations, muscle pains and later cough which characteristically was productive of thick, greenish-yellow sputum. Gastro-intestinal symptoms were not infrequent and included nausea, vomiting, diarrhea and sometimes abdominal pain. Of the nervous symptoms noted, there were delirium, meningismus and rarely melancholia or dementia.

Physical examination revealed flushed face, injected conjunctivae, and erythematous rash of the face, neck and shoulders. The mucous membrane of the soft palate and pharynx was injected and sometimes presented petechial hemorrhages. The pulse rate was increased; the respirations ranged between 20 and 30 per minute, and the temperature from 101 to 104 F. Leukopenia was the rule, and the average leukocyte count of twenty-five influenza patients was 6,500. In uncomplicated cases the average stay in the hospital was seven days.

Pneumonia was the most serious complication. It is to be suspected in patients whose temperature remains high after the sixth or seventh day. The early chest findings were obscure. Later, patchy consolidation usually could be demonstrated. In the grave cases marked cyanosis of the patient was common. A moderate leukocytosis of from 12,000 to 16,000 was usually observed. Other common complications were empyema, otitis media, sinusitis, meningismus and jaundice.

MORBID ANATOMY

The external appearance of the bodies of those who had died from influenzal pneumonia was characteristic.

The postmortem lividity was extensive, involving the head, trunk and extremities. Not infrequently a bloody, frothy fluid exuded from the nostrils and mouth.

The tracheobronchial mucosa was generally reddened, and the small blood vessels were engorged. In their lumens, mucous, mucopurulent or hemorrhagic secretion was present. The tracheobronchial lymph glands were usually engorged with blood and were edematous.

Early in the disease, the lung involvement was chiefly lobular, with hemorrhagic, catarrhal or purulent exudate containing scarcely no fibrin. The surfaces made by cutting were mottled, firm and granular, with dark red congested areas of aerated lung tissue intervening. Large quantities of bloody fluid bathed the cut surfaces. Thick purulent material commonly oozed from the small bronchi. Serous or serosanguineous fluid was frequently found in the pleural cavities. Later in the course of the disease, the amount of fibrin increased and the exudate became gray and often purulent. Plastic pleuritis was not infrequent. It was noteworthy that at two necropsies, empyema was present with the pus between the mediastinal pleura and the hilum of the lung, while the lateral surface of the lung was adherent to the chest wall by fibrinous adhesions, causing obliteration of the pleural cavity. This finding accounted for the inability to aspirate pus on thoracocentesis after empyema had been diagnosed in the ward.

The liver and kidneys were usually heavier than normal and were the seat of parenchymatous and fatty changes.

TECHNIC OF BACTERIOLOGIC STUDIES

Beef infusion agar and broth were the two basic mediums used. The reaction was adjusted to neutrality to phenolphthalein before autoclaving. For cultivating *B. influenzae*,

Chart 2.—The relationship of age to the number of admissions (solid line) and deaths (broken line) during the epidemic period.

the agar at 90 C. was enriched by the addition of 5 per cent. defibrinated horse blood. Plates were poured after this added blood had become a chocolate brown. These agar surfaces were inoculated from throat swabs and with the sputum of the patients studied. In the early studies, sputum was injected intraperitoneally into white mice, and plate cultures were made from the peritoneal exudate and from the heart blood of the mouse at necropsy. This was later discontinued when it became apparent that in practically all cases *B. influenzae* was demonstrable in direct cultures of the throat or sputum.

2. Keeton, R. W., and Cushman, A. B.: The Influenza Epidemic in Chicago, J. A. M. A. 71: 1962-1967 (Dec. 14) 1918.

Well separated giant colonies of *B. influenzae* were usually to be found on these plates, and pure cultures could easily be recovered. The identification of *B. influenzae* rested on its cultural characteristics on the brown blood agar, and its failure to grow on hemoglobin-free agar, as well as its morphologic and staining characteristics.

For pneumococcus identification and typing, the mouse method was used, freshly collected sputum being employed. Red blood plate cultures were made from the peritoneal exudate and from the heart blood of the mouse at necropsy; and single colonies of pneumococcus, picked from these plates, were grown on red blood agar slants. After about eighteen hours' incubation, a tube (5 c.c.) of infusion broth was poured over the slant and incubation continued for a period sufficient to yield adequate growth in the broth for agglutination and bile solubility tests.

In the ward surveys for hemolytic streptococci, this technic was employed:

Beef infusion agar (0.3 per cent. acid to phenolphthalein) was prepared and stored in from 300 to 500 c.c. amounts. On melting and cooling the agar below 45 C., sterile defibrinated horse blood was added in amounts sufficient to make up 5 per cent. of the volume of the agar. Thorough mixing and pouring into petri dishes (10 cm. in diameter) followed.

Throat cultures of all patients in the ward were made on the day of study. In taking the culture, a small cotton swab was touched first to the posterior pharyngeal wall in order to produce gagging. This caused the tonsils to protrude toward the midline and placed a slight tension on the capsule, which tended to press material from the crypts. The surfaces of both tonsils thus protruding were quickly brushed and the swab withdrawn without touching other parts. These swabs were carried to the laboratory in sterile test tubes and were used at once to inoculate the blood agar plate surfaces.

The swab was touched lightly to the agar surface at two points, one near each extremity of a given diameter of the plate. The swab stick was turned between the fingers through one revolution so as to bring all points of the swab in contact with the agar. The inoculum was spread by means of an inoculating wire slightly curved at the end. After passing the wire several times over the points of inoculation, multiple streaks and cross streaks were made, avoiding further contact with the points of primary inoculation. With a little experience this method furnished well seeded plates, presenting colonies widely enough separated to render plate reading easy.

Careful preparation of mediums, and a rigid technic for throat swabbing and for seeding the plates are prime requisites which cannot be emphasized too strongly in any method of direct throat culture. Lack of care in any one of these particulars does much to vitiate the results obtained. In properly prepared cultures, the recognition of hemolytic streptococci is very simple.

In these ward surveys, plate readings, supplemented by a Gram stain of typical hemolytic colonies, were employed as the means of identification of hemolytic streptococcus carriers. Colonies producing typical hemolytic zones of the Beta type of streptococcus (Smith and Brown) were picked from all cultures in which they appeared after twenty-four hours' incubation, and were stained. Cultures presenting hemolytic colonies, which on staining showed gram-positive cocci in chains, were regarded as positive for hemolytic streptococci. Further confirmatory studies were not made.

These surveys at ten day intervals were instituted to determine the prevalence of hemolytic streptococci in the wards rather than to follow the bacteriology of any particular patient. They were employed as a clinical aid in a system of ward management aimed at minimizing dangerous contact dissemination of hemo-

lytic streptococci. The methods used enabled the prompt reporting of hemolytic streptococcus carriers and their early isolation, both of which are matters of extreme importance in the management of wards caring for influenza and pneumonia patients.

STUDIES OF ACUTE INFLUENZA

A group of twenty-two patients was studied by means of throat and sputum cultures on brown blood agar, together with the inoculation of sputum into the peritoneal cavities of white mice, and subsequent cultures of the peritoneal exudate and the heart blood were made both on red and brown blood agar plates. This triple means of study enabled a determination of the occurrence of *B. influenzae*, pneumococcus and hemolytic streptococcus, which was: *B. influenzae*, twenty-two times, or 100 per cent.; pneumococcus, Type I, none; Type II, one; Type II, atypical, five; Type III, one, and Type IV, nine; total, sixteen, or 72.7 per cent.; hemolytic streptococcus, twice, or 9.1 per cent.

A second group comprises forty-five cases of acute influenza, which were studied only by throat and sputum cultures. These cultures were made on the brown blood agar, and no attempt was made to identify organisms other than *B. influenzae*. *B. influenzae* was isolated and identified in forty-three of these cases, or in 95.5 per cent. Of this group, cultures were made of eighteen patients in the receiving ward of the hospital, of which number, only throat cultures were made in six cases. The two patients that were negative for *B. influenzae* were in this group of six.

In the first series in which a study was made by all three methods, *B. influenzae* was found in 100 per cent. of the cases. These results are in accord with those obtained last year at Camp Pike by Opie³ and his co-workers.

The second group demonstrates that *B. influenzae* can be found in practically every case by the less elaborate methods, when cultures are made on brown blood medium. It should be emphasized that this medium appears to be more or less selective for growing the Pfeiffer bacillus.

BACILLUS INFLUENZAE IN NONINFLUENZAL PATIENTS

Cultures for *B. influenzae* were made of a group of patients, with conditions other than influenza or other respiratory diseases, examined in the receiving wards of the hospital during the height of the epidemic. Of the thirty patients of whose throats and sputums cultures were made, *B. influenzae* was isolated in twenty-one, or 70 per cent.

In a second series, twenty-six patients hospitalized before the epidemic in the tuberculosis ward, *B. influenzae* was identified in sputum and throat cultures in nine instances, or 34.6 per cent.

These studies furnish two control series. The first represents patients arriving at the hospital during the height of the epidemic, and can be regarded as a group showing the prevalence of the Pfeiffer bacillus in persons outside the hospital during the period of the epidemic. The relatively high incidence of this organism in the foregoing series is comparable to the reported findings⁴ in normal persons during the pan-

demic of 1918, and may be regarded as illustrating the wide dissemination of the bacillus during epidemic periods.

The second group represents patients hospitalized before the epidemic, and may be regarded as illustrating the prevalence of Pfeiffer's bacillus during the interepidemic periods.

PNEUMONIA STUDIES

A group of thirty-two cases studied bacteriologically presents the bacteriology of the pneumonia of influenza as it occurred in cases chosen at intervals in the hospital wards throughout the course of the epidemic.

The occurrence of the various organisms was: pneumococcus, Type I, two times; Type II, one; Type II, atypical, six; Type III, five; Type IV, thirteen; total, twenty-seven, or 84.4 per cent.; hemolytic streptococci with pneumococci, one; with no pneumococci, five; total, six, or 18.7 per cent.; *B. influenzae*, twenty-four, or 75 per cent.

The types of pneumococci occurring in the mouths of normal persons were found in practically 90 per cent. of the pneumococcus pneumonia cases of this group. The parasitic types, I and II, occurred infrequently, Type I only twice, and Type II once. These findings are in accord with those reported for the pneumonia of the 1918 pandemic of influenza by various observers.

Hemolytic streptococci occurred in approximately one fifth of the cases. In those studied early, hemolytic streptococci were not found. All instances in this group in which hemolytic streptococci appeared were among patients studied within the latter half of the epidemic. *B. influenzae* was present in three fourths of these cases.

WARD SURVEYS FOR IDENTIFICATION OF HEMOLYTIC STREPTOCOCCI

The dissemination of hemolytic streptococci throughout wards in which acute respiratory diseases were treated, and the dangers attending such dissemination, have been emphasized recently.⁵ In two of the wards, throat cultures of all patients under treatment were made at intervals of about ten days. The cultural methods have been described. Since many cases of

Feb. 12	4	2	50.0

pneumonia terminated fatally in less than ten days and many patients with influenza were discharged within a shorter period than this, the study furnishes few repeated cultures on individual patients during the course of their illness. The repeated ward surveys indicate the incidence of hemolytic streptococci in the wards during the period of their use for the care of influenza and pneumonia patients. The results of this study have been:

1. In Ward A, from January 18 to February 13, the total number of patients treated was 125; the total num-

ber of pneumonia patients treated in the ward was fifty-seven, and the total number of deaths in the ward was forty-one.

Of the four patients positive for hemolytic streptococci on the first survey, three developed no complications of influenza and left the hospital before recultures were made of the patients in the ward. They had been in the hospital four, six and seven days, respectively, before cultures were taken. The fourth patient was admitted with influenzal pneumonia nine days before the culture was made, and died of pneumonia, January 28. Cultures had been taken previously of each of the three patients identified as hemolytic strep-

TABLE 2.—RESULTS OF CULTURES TAKEN FOR
HEMOLYTIC STREPTOCOCCI IN WARD B

Cultures		Cultures Positive for Hemolytic Streptococci

tococcus carriers on the second and third ward surveys and had been found to be negative. They were patients that had acquired hemolytic streptococci in the hospital. Two of these patients had pneumonia on admission. Both died: the first, three days after the identification; the second, eight days after the identification. In neither patient was a diagnosis of empyema made.

The results show that the incidence of hemolytic streptococci in this ward was never high. The complications (other than pneumonia) developing among the fifty-two patients studied are in accord with this finding. They are two cases of empyema, one due to pneumococcus Type II, atypical, and the other showed *Streptococcus viridans* and staphylococci on culture. One case of otitis media occurred, the bacteriology of which was not determined.

2. In Ward B, from January 19 to February 13, the total number of patients treated was 184; the total number of pneumonia patients treated in the ward was 101, and the total number of deaths in the ward was fifty-six.

The figures in Table 2 indicate that there was a wider dissemination of hemolytic streptococci in Ward B than in Ward A. Four cases of empyema occurred in Ward B, all due to hemolytic streptococci.

Of the fifteen patients whose throats gave cultures positive for hemolytic streptococci, January 24, five had pneumonia. Three recovered without further complication. The fourth died of pneumonia, and the fifth developed a hemolytic streptococcus empyema, diagnosed, January 4, and is at present under treatment in a surgical ward. The remaining ten were patients with influenza, of which number, all recovered without complication.

Of the fourteen patients whose throats gave cultures positive for hemolytic streptococci, February 3, twelve had pneumonia, of which number, two had been positive and one negative for hemolytic streptococci on previous culture. Of the remaining nine, two developed hemolytic streptococcus empyema. One of these died, February 7; the other is convalescent. Of the remaining seven patients, one died of pneumonia. Two patients with influenza recovered without complication.

Previous cultures had been made in the twelve cases, positive, February 12. One patient had had two posi-

5. Opie, et al. (Footnote 3). Cole, Rufus, and MacCallum, W. G.: Pneumonia at a Base Hospital, J. A. M. A. 70: 1146 (April 20) 1918. Levy, R. L., and Alexander, H. L.: The Predisposition of Streptococcus Carriers to the Complications of Measles, J. A. M. A. 70: 1827 (June 15) 1918.

tive and another one positive culture. Both recovered from the pneumonia without complication. Of the remaining ten patients negative on previous cultures, one recovered from uncomplicated influenza, and nine had pneumonia. One died of uncomplicated pneumonia, February 15. Two were discharged as recovered. Six are under treatment for pneumonia, and two of these have developed otitis media.

In addition to the complications mentioned, a few cases of otitis media developed among patients whose throat cultures were negative for hemolytic streptococci. The bacteriology of the cases of otitis media was not determined.

The red blood agar plates used in the ward surveys for hemolytic streptococci were also studied for *B. influenzae*. These results are of interest in showing the relative incidence of *B. influenzae* among the ward patients studied at various intervals throughout the course of the epidemic. They are not presented to give actual incidence of *B. influenzae* because the methods employed are less reliable for the isolation of this bacillus than those employed for determining actual incidence.

A summary of the studies of the cases in the two wards is given in Table 3.

It has been mentioned that early in the course of the epidemic the wards had under treatment more patients with influenza than with pneumonia, but that later the number of patients with pneumonia predominated. In the summary given in Table 3, all ward patients were

included, i. e., both influenza and pneumonia patients. The results indicate a decrease in the relative incidence of *B. influenzae* in the later periods of the epidemic when the larger part of the patients in the wards had pneumonia.

SUMMARY

About one third as many patients suffering from influenza or its complicating pneumonia were treated in this hospital during the present epidemic as were treated during the pandemic of 1918.

Of the 829 patients whose cases were analyzed, 503, or 60.7 per cent., were admitted with a diagnosis of influenza, and 326, or 39.3 per cent., with a diagnosis of pneumonia. Many of the latter were moribund on admission to the hospital. Of these 326 pneumonia patients, 205 died, a mortality rate of 62.9 per cent.

Forty-six, or 9.1 per cent., of the patients admitted with influenza developed pneumonia, and twenty-six, or 47.8 per cent., of these died.

B. influenzae was isolated by the multiple culture methods from 100 per cent. of the patients studied, and by the direct sputum and throat culture method from 95.5 per cent.

Pneumococci were found in 84.4 per cent. of the cases of pneumonia studied, and for the most part are represented by the types of pneumococci found in the mouths of normal persons. Hemolytic streptococci were found in 18.7 per cent., and *B. influenzae* in 75 per cent. of these cases of pneumonia.

One of the wards showing active dissemination of hemolytic streptococci furnished four cases of empyema, all due to hemolytic streptococci. Two cases of empyema, both due to organisms other than hemolytic streptococci, occurred in a second ward where these organisms were less prevalent.

CONCLUSION

B. influenzae has been isolated and identified in 100 per cent. of the cases of acute influenza.

In the cases of pneumonia complicating influenza, pneumococci predominate. They are chiefly of the types found in the mouths of normal persons.

Hemolytic streptococci occupy a prominent place in the complications of influenza and pneumonia.

ADDENDUM

We believe that a brief statement as to the hospital management during the epidemic will be valuable to illustrate the conditions under which these studies were conducted.

By condensing medical and surgical services, five wards were rendered available for the treatment of influenza and pneumonia patients admitted to the hospital during the period of the epidemic. These wards were opened one after another as needed. The wards were filled to capacity in the order in which they were opened. After the fifth ward had been filled, sufficient beds were becoming available in other wards to care for patients admitted subsequently.

Influenza and influenzal pneumonia patients were not treated in separate wards. Early in the epidemic period there were fewer pneumonia and more influenza patients than later when the pneumonia patients predominated among the admissions. In the latter part of the period the treatment wards became literally pneumonia treatment wards, the segregated uncomplicated influenza patients occupying much the smaller sections of the wards. The wards were supplied with sheet cubicles and otherwise equipped before receiving any patients.

These rules for the management within the wards were issued on the opening of the wards and served as a basis of the plan of ward management throughout the epidemic:

The cubicle system is to be used in all wards.

Paper bags will be provided and must be used for soiled napkins and gauze.

Hand disinfectant solutions will be provided for use by the physicians, nurses and attendants in passing from one patient to another.

Ward floors should not be dry swept, but must be scrubbed at intervals with compound solution of cresol in the water.

All physicians, nurses and attendants are required to wear gowns, caps and masks while in the ward.

Bed patients are not required to wear masks, but the mask will be strictly enforced on all patients leaving the cubicle.

Paper napkins are to be provided for bed patients, who will be instructed to cover the mouth and nose on coughing, sneezing, etc. These must be changed when soiled.

Attempt will be made to keep acute cases of influenza in the same section of the ward.

Attempt will be made to prevent the congregating of convalescents in toilets, bath rooms, etc.

The borrowing and lending of materials between the patients is to be strictly prohibited.

Pneumonia developing in the influenza wards will be treated in separate sections of the wards, and medical asepsis strictly enforced in such section.

Cases of streptococcus pneumonia must be treated apart from those of pneumococcus pneumonia.

THE DELIRIOUS AND THE MENINGO-RADICULAR TYPES OF EPIDEMIC ENCEPHALITIS

PETER BASOE, M.D.

Associate Professor of Nervous and Mental Diseases, Rush Medical College
CHICAGO

Since my last report¹ of a number of cases of epidemic encephalitis, I have become convinced that the same unknown virus produces clinical forms in which lethargy and other common symptoms of the characteristic "lethargic" form may be lacking. That we are dealing with the same disease is shown by the similarity in pathologic anatomy, the existence of transitional forms, and the occurrence of all these forms in the same community at the same time. Among the cases observed during the past winter, several have presented severe symptoms of a general infection suggestive of typhoid fever, acute miliary tuberculosis or other acute infectious disease. In other cases, verified by necropsy, the resemblance to severe, acute chorea was marked. Among new symptoms I, too, have observed the twitching of the abdominal muscles to which Thomas F. Reilly² has recently called attention.

One patient, now improving, had complete right hemiplegia with aphasia, and another patient, who died, had at different periods right and left hemi-

the so-called "infective neuronitis,"³ and will be discussed at the end of this paper.

REPORT OF CASES

CASE 1.—History.—A man, aged 36, seen at the Evanston Hospital with Drs. W. G. Alexander and W. G. Stearns, Nov. 12, 1919, two weeks previously when in an exhausted state from overwork and worry, had commenced to complain of headache, and pain in the right side of the neck and left arm. He became irrational, November 6, and on November

Fig. 2 (Case 3).—Motor cortex, deep layer: degenerated ganglion cell and satellites; $\times 1,200$.

Fig. 1 (Case 3).—Motor cortex: congestion, hemorrhages, and edema of the pia; hematoxylin and eosin, $\times 25$.

plegia. Pain in the extremities was a marked feature in a few otherwise typical cases, and serves to connect them with the type which I propose to designate "meningoradicular." This bears some resemblance to

7 developed diaphragmatic spasms which lasted for five days. The highest temperature observed prior to his admittance to the hospital, November 9, was 100.2 F. From November 9 to 16 it ranged from 100 to 102, pulse, 90 to 110, respirations, 20 to 25; November 18, the temperature was 102.2, then from 100 to 101 until November 26, after which time it was usually between 99 and 100. November 11, Dr. Stearns recorded "involuntary, irregular contractions of the diaphragm, extending over the upper trunk muscles, and accompanied by more or less coarse tremor."

Examination and Course.—The leukocyte count, November 11, was 17,600; November 12, 26,200; November 13, 19,000; November 19, 12,800; November 28, 9,200; December 8, 12,800; December 19, 12,600. November 12, Dr. C. J. Swan noted "spontaneous nystagmus which does not seem to be labyrinthine but is synchronous with contractions of the body muscles. Fundi normal." On that day I failed to find any paralysis or any abnormality in the reflexes. The patient was very restless and delirious, and the diaphragmatic spasm was continuous. On the following day, partial left ptosis appeared and remained a few days, and on November 29 transient right ptosis appeared. Lumbar punctures, November 14 and 25, yielded a fluid admixed with blood, so that cell count and globulin tests were of little value; but cultures with both blood and spinal fluid were negative. A clear fluid, obtained November 22, gave negative globulin and Wassermann tests and a cell count of 18. The Wassermann test with the blood was negative. While comparatively clear mentally part of the time, he was described, December 21, as stuporous and at times delirious, and at that time had to be catheterized for two days. During January he steadily improved, and by the middle of the month began to sit up. The mental condition became normal. In March he was said to be well.

CASE 2.—History.—A man, aged 38, seen at the Highland Park Hospital with Dr. L. M. Bergen, Nov. '3, 1919, had

1. Basoe, Peter: Epidemic Encephalitis (Nona), J. A. M. A. 72: 971 (April 5), 1919.

2. Reilly, T. F.: Hitherto Undescribed Sign in Diagnosis of Lethargic Encephalitis, J. A. M. A. 74: 735 (March 13) 1920.

3. Kennedy, Foster: Infective Neuronitis, Arch. Neurol. & Psychiat. 2: 621 (Dec.) 1919.

complained of pain in the face and body, November 6, and took to his bed. The pain lasted only one day. After three days he became delirious and was admitted to the hospital in a state of restless delirium, November 11, with a temperature of 99.8, pulse, 116; respirations, 20. Insomnia was a marked feature.

Examination and Course.—November 12, the leukocyte count was 9,000; urine, normal. When seen in the evening of

mally. The tendon reflexes and the abdominal reflexes were not obtained, while the plantar reflexes were normal. The heart and lungs were negative. The urine contained albumin, and one granular cast was seen. Lumbar puncture yielded a clear fluid under normal pressure with a cell count of 150 lymphocytes, negative Nonne-Apelt globulin test, and a practically negative Lange test (0011100000). The temperature, January 31, ranged from 102 to 103.6; the pulse rate from 110 to 132. January 1, the delirium and continuous movements persisted and the temperature rose from 102.4 to 106.4. She died at noon on that day.

Necropsy.—Dr. Beers informed me that the viscera were normal except for cloudy swelling of the liver. The brain, when received by me in 10 per cent. liquor formaldehydi, presented no gross changes externally or on section except considerable congestion. No hemorrhages were visible to the naked eye.

Histologic Examination: Lower medulla: very slight mononuclear infiltration of pia; well marked perivascular infiltration throughout; cells mononuclear. Upper medulla: similar changes but less marked; very little change in the ganglion cells. Cerebellum: very slight cell infiltration of meninges; no distinct perivascular infiltrations; some of the Purkinje cells showed degenerative changes with their nuclei obscured and presence of satellites. Pons: meningeal cell infiltration slightly more marked than in medulla; one small subpial hemorrhage was seen, also a very few and small recent hemorrhages in the interior; several fairly dense perivascular infiltrations were present. Crus and midbrain: perivascular infiltrations similar to those in lower medulla; a few small hemorrhages were seen; ganglion cells were, on the whole, well preserved, and satellitosis was slight; there was no distinct perivascular infiltration. Right motor cortex: pia congested with extensive hemorrhage in one of the sulci, but only slight cellular infiltration; cortical vessels engorged with a slight increase in lymphocytes in the adventitia, but no distinct perivascular collars; the ganglion cells took the stain well and had distinct nuclei; satellitosis was rather pronounced, especially about the smaller cells; a few ganglion cells were decidedly degenerated, with loss of nucleus and pulverization of the Nissl bodies; other cells appeared narrow, with total loss of cell structure (cell sclerosis); some

Fig. 3 (Case 3).—Lower bulb; perivascular infiltration; $\times 85$.

November 12, he was extremely restless and constantly fumbled with the bedclothes, but he was oriented and answered questions. The temperature on that day reached 102; pulse, 126; respiration, 28. General examination of the abdominal and thoracic viscera was negative. There was no paralysis, nor were there other positive neurologic findings. The Widal and Wassermann tests were negative. The patient became cyanotic and died the same evening. No necropsy was held.

CASE 3.—History.—A girl, aged 16, with negative previous history, seen at the Grant Hospital with Dr. Bertram R. Beers, Dec. 31, 1919, began, a week before, to complain of slight pain in the left leg and the left side of the body, and general malaise. Later, jerky movements set in; but little attention was paid to her trouble until December 29, when she had an attack in which she became rigid, frothed at the mouth and screamed. Afterward she was unable to talk for a time. Late in the evening of that day she was admitted to the hospital with a temperature of 100.8; pulse, 84; respirations, 20. During her stay in the hospital she was actively delirious and constantly threw herself about. She used the right side of the face and the right arm more than the left. She frequently struck at the physicians with her right arm. There were involuntary discharges of urine and feces. The temperature, December 30, ranged from 101 to 102; pulse, from 80 to 112.

Examination.—Blood examination revealed: hemoglobin, 85 per cent.; red cells, 4,680,000; white cells, 27,600 (polymorphonuclears, 82 per cent.; small mononuclears, 16 per cent.; large mononuclears, 2 per cent.). When examined, December 31, the patient could only whisper unintelligibly and was in a state of active delirium. She had a heavily coated tongue, sordes on the teeth, cracked lips, and acetone odor of the breath. The right pupil was larger than the left and reacted poorly to light, while the left one reacted nor-

Fig. 4 (Case 4).—Cerebellum: below, degenerated Purkinje's cell, surrounded by phagocytic cells; above, well preserved Purkinje's cell; toluidin blue, $\times 540$.

of the smaller ganglion cells were invaded by two or three neuronophages. Right occipital lobe: no pial hemorrhage, and congestion less marked; cell changes less marked than in motor cortex. Right frontal: pial congestion quite marked, with slight hemorrhage; few small extravasations seen in the cortex; many small ganglion cells much degenerated:

the same was true of a few of the larger ones; satellitosis was quite common; neuronophagia was extremely rare.

CASE 4.—History.—A high-school girl, aged 17, seen on Jan. 15, 1920, with Dr. Kate Graves, had been quite tired from working in a store during her Christmas vacation. January 2, a very cold day, she had been skating, and felt ill in the evening. The next morning she had occipital headache, and chills in the afternoon, followed by severe tooth-

mann test was negative. The Nonne-Apel't globulin test was positive; cell count, 72; Lange gold test, negative.

On the evening of the 15th she slept for three hours without a hypnotic. In the morning she was quite rational and quiet, but had much difficulty in clearing her throat. She became unable to swallow, and mucus rapidly accumulated in the throat. She grew cyanotic and died at 1 p. m., January 16. The maximum temperature on that day was 100.6; pulse, 100; respirations, 34.

Necropsy.—A limited necropsy was made six hours after death. There was no fluid in the pleural or peritoneal cavities. The lungs contained no consolidated areas, and the abdominal viscera were normal externally. Small pieces were removed for histologic examination; otherwise the organs were not incised. The cerebral meninges were normal and there was no evidence of inflammation in the sphenoid or ethmoid sinuses. The brain showed no changes externally or on the cut surfaces when sectioned after formaldehyd hardening. The brain weighed 1,200 gm. Blood-agar cultures of the cerebrospinal fluid obtained at the base of the brain remained sterile.

Histologic Examination: Cerebellum: considerable pial infiltration with mononuclear cells; marked congestion and occasional slight extravasation in pial septums; many Purkinje cells were degenerated and surrounded by satellites. Cervical cord: considerable cell infiltration and marked distention of vessels at the ventral median fissure; large perivascular infiltrations in gray and in white matter, and in all parts of the transverse section; gray and white matter about equally involved. Lower medulla: very large and numerous perivascular infiltrations throughout the cut surface; also, much diffuse round cell infiltration. Upper medulla: pial infiltration marked, especially laterally; much less marked in ventral fissure than in same fissure of cord; vascular infiltrations especially marked near floor of fourth ventricle, but present throughout; ganglion cells preserved, but surrounded and invaded by inflammatory cells. Midbrain with aqueduct: numerous perivascular infiltrations and considerable hemorrhage. Optic thalamus: very little inflammation; no large infiltrations. Cerebral cortex: slight pial infiltration; considerable satellitosis about the small ganglion cells in the deeper layers of the cortex.

Fig. 5 (Case 4).—Upper cervical cord, posterior horn and surrounding white matter: perivascular and diffuse inflammation; toluidin blue, $\times 90$.

ache for which a dentist could find no cause. January 4, she had pain about the left eye and in front of the left ear, but no fever.

The patient went to bed that day, felt better on the 5th, and on the 6th she had pain in the left shoulder. From the 6th to the 11th she had very rapid breathing without any chest findings, with no acceleration of pulse, and the temperature did not exceed 99.4. On the 10th she was troubled with mucus in the nose, was nauseated and quite hysterical and delirious, seemed to have hallucinations of sight and hearing, and wanted water every few minutes; she said she could not breathe without it. From the 12th a nurse was in attendance, so that a temperature record was kept. On that day the highest temperature (axilla) was 100; pulse, 120; respirations, 40. She was restless and perspired freely. She had some disturbed sleep after taking paraldehyd. On the 13th the temperature ranged from 100.6 to 101.2; pulse, 98 to 108; respirations, 26 to 42. On the 14th, temperature, 99.5 to 100.6; pulse, 96 to 102. She was restless and was quieted by paraldehyd and luminal. On the 15th the temperature and pulse were about the same. Since the 10th she had been having jerky and twitching movements of the face and extremities; double vision was complained of on the 11th, 12th and 13th.

Examination and Course.—January 15, the patient was very drowsy; she did not cooperate in the examination. No choreic or other movements were observed. The pupils were small and equal, and reacted to light. The plantar reflexes were normal; the abdominal and ankle reflexes were not obtained. The right knee reflex was present, the left, absent. There was a weak systolic murmur at the apex. Herpes appeared on the right lip and erythematous patches on the right cheek and right side of the chest. Lumbar puncture yielded a clear fluid under normal pressure. The Wasser-

Fig. 6 (Case 4).—Lower bulb, near central canal: perivascular infiltration of mononuclear cells, denser about veins (to left), than about artery.

Comment on Histologic Findings.—It will be noted that essentially the changes are the same as in the ordinary lethargic form. The mononuclear cell infiltrations are most marked in the bulb, pons and cord, while the basal ganglions show surprisingly little involvement. On the other hand, the pial infiltration over the cerebral cortex is relatively marked.

"MENINGORADICULAR" TYPE

With some hesitation I suggest that this virus also may produce a syndrome characterized by meningeal irritation, and by irritation or paralysis referable to the spinal or cranial nerve roots.

CASE 5.—History.—A man, aged 34, seen, April 8, 1919, with Dr. H. F. Langhorst of Elmhurst, Ill., had been taken with vomiting and diarrhea four days before. The next day his temperature was 100, and he had severe pain in the left side of the neck and the left shoulder. The following day he felt better and walked about, but on April 7 he became unable to extend the right hand and to hold the head up. There was pain at the back of the neck.

Examination and Course.—April 8, the neck muscles were weak and active movements painful. There was paralysis of the extensors of the fingers of both hands. The abdominal muscles and flexors of the hips were weak. There was no other paralysis. Sensation was normal. All tendon reflexes were present, but those in the arms were weak. There was no mental disturbance at any time. The pulse was slow (56). Lumbar puncture yielded a clear fluid under increased pressure with a cell count of 20, and weakly positive globulin test and Lange gold test (0122111000). The patient rapidly improved. April 12, he was able to walk about, and complained only of slight numbness in the fingers and toes. He recovered completely.

CASE 6.—History.—A business man, aged 39, with negative previous history aside from right-sided facial paralysis of a few days' duration three years before, admitted to the Presbyterian Hospital, Jan. 27, 1920, six weeks previously had been taken with pain and stiffness of the neck, and later, with pain in both shoulders and arms. January 2, he had fever and delirium which lasted two days. January 4, he became unable to close his right eye or close the mouth tightly on

tally clear. Lumbar puncture, January 27, yielded a clear fluid under greatly increased pressure; cell count, 16; Nonne-Apelt globulin test, positive; Lange gold test, positive (0123221000); Wassermann test negative with blood and spinal fluid. Blood count: hemoglobin, 100 per cent.; erythrocytes, 4,150,000; leukocytes, 9,800. The patient slept poorly on account of pain in the arms. A second lumbar

Fig. 8 (Case 4).—Motor cortex, deep layer: degenerated ganglion cells with satellites; toluidin blue, $\times 900$.

puncture, January 31, yielded clear fluid under normal pressure, 9 cells; globulin test, positive; Lange gold test weaker (0001221100). The maximum temperature at the hospital was 99.2. The patient still complained of pain in the arms when he went home, February 2, but was reported as having recovered by the end of the month.

Comment.—The right-sided facial paralysis and the condition of the reflexes on the left side of the body suggest a mild pons lesion. The facial nerve may have been involved at its exit from the pons or in its nucleus. The high pressure of the spinal fluid indicates serous meningitis, while the pain in the arms and neck was probably caused by root irritation, as there was no paralysis or sensory disturbance, nor atrophy or change in the reflexes in the arms. The involvement in this case was sufficiently extensive to merit the term "meningo-encephalomyeloneuritis," used by Barker, Cross and Irwin⁴.

30 North Michigan Avenue.

4. Barker, Cross and Irwin: *Am. J. M. Sc.* 159: 157 (Feb.) 1920.

Influenza an Ancient Disease.—In his special report on influenza to the London county council, Dr. H. W. Hamer gives an account of the prevalence of the disease in London with reference to contemporary outbreaks in other parts of the world and reviews the occurrence of similar epidemics in bygone years. Dr. Hamer draws some very instructive parallels between this last epidemic and the "sweats," "hot agues," "spotted fevers," and certain so-called "new diseases," all more or less of an influenzal type, which have been described by writers in the fifteenth, sixteenth and early part of the seventeenth centuries. These also were apparently associated with other diseases of an allied type, in which cerebral symptoms predominated, and he points out that the history of the "new fever" of 1685 bears a close resemblance to the 1915 outbreak of influenza in London, plus cerebrospinal fever. Dr. Hamer extracts from the old writers a mass of strikingly suggestive evidence, in which the quaint terse terms used by them to describe the outstanding features of the epidemics are almost as conclusive as the more elaborate nomenclature of modern physicians.

Fig. 7 (Case 4).—Upper bulb, dorsal surface: perivascular infiltration; toluidin blue, $\times 70$.

the right side. When admitted to the hospital his chief complaint was pain in both forearms and hands.

Examination and Course.—The chief findings were: slight right-sided facial paralysis of peripheral type, increased knee reflexes, more so on the left side; left Babinski sign, left lower abdominal reflex absent; other abdominal reflexes normal. Muscular tenderness of forearms and hands. Men-

TUBING AS A CAUSE OF REACTION TO
INTRAVENOUS INJECTION, ESPE-
CIALLY OF ARSPHENAMIN

PRELIMINARY REPORT *

JOHN H. STOKES, M.D.

Associate Professor in Medicine, the Mayo Foundation

G. J. BUSMAN, M.D.

Fellow in Dermatology and Syphilology, the Mayo Foundation

ROCHESTER, MINN.

During the last two years we have been investigating the cause of an arsphenamin reaction observed on the service of the Section on Dermatology and Syphilology. This reaction, characterized by a chill with a sharp rise in temperature coming on from thirty minutes to an hour after intravenous injection, accompanied by nausea, vomiting, diarrhea, pain in the head and back and varying degrees of prostration, would appear in crops, so to speak, and then disappear for a considerable period, only to recur in the very midst of what seemed a period of flawless technical accuracy. Repeated efforts to identify a cause in the water or the chemicals employed in the preparation of arsphenamin for injection yielded nothing definite. The first clue to the actual cause was afforded by the appearance of a series of reactions, Jan. 6, 1919, following the transfer of the hospital and operating room service of the section from the Colonial Hospital to the Worrell Hospital. On this day every element in the technic except one remained the same as on the last day at the Colonial, when no reactions had occurred. The old piece of supposedly pure gum rubber tubing used on the glass container on the final reactionless day at the Colonial was replaced by the new piece of pure gum rubber tubing used on the opening day of many reactions at the Worrell. One of us (Busman), who was administering the arsphenamin at this time, suggested that the new tube was responsible for the reactions, although its cleaning and sterilization had been carried out with the same care used in the case of the old tube. Starting with this suggestion, we have carried the investigation of the "tubing reaction" to the point at which a preliminary report of the work seems desirable in order that physicians generally may be placed on their guard. One of us (Stokes), viewing the matter in retrospect, can recall two "epidemics" of similar reactions in his own experience on another service, which were attributed at the time to contamination of the distilled water. Study of the literature of crops of reactions, notably in army camps, also offers some

points of suggestive comparison with our own experience. The possibility that a reaction of this type forms a complication of intravenous injections of alkaline solutions given through a brand of tubing known to produce this reaction, and the possible relation of the tubing to certain reactions occurring in blood transfusion by the citrate method as employed in the Mayo Clinic, are also under investigation.

At the time of the operating room transfer, all fourteen patients who received arsphenamin through the new tube reacted. On the following day, fifteen of eighteen patients reacted to another new tube. Four and one-half months later, when another change of tubing became necessary, an old and a new tube were checked against each other, identical lots of arsphenamin prepared in identically the same manner being employed. On the first day, in twelve of thirteen

cases reaction followed the giving of the arsphenamin through the new tube, and no reaction occurred in nine cases in which arsphenamin was given through the old one. On the second day, arsphenamin given through the new tube of the previous day produced chills in three cases, nausea in four, and headaches in six, of ten cases. Absolutely no reaction had followed fourteen injections of the same arsphenamin solution through the old tube. On the third day there were no reactions from either tube.

Dec. 8, 1919, seven months after this experience, it again became necessary to replace worn out tubing, and on this occasion also all the patients who received arsphenamin through new tubing the first day reacted markedly. On the second day, the reactions to the arsphenamin through the new tubing were slight. None of the patients who received the solution through old tubing had the slightest reaction. On the third day, all tendency to reaction disappeared.

These seemingly convincing demonstrations incriminating the tubing led us to make efforts to ascertain the cause of the toxicity and to devise methods for its removal or the abatement of its effects. A variety of hypothetic possibilities presented themselves:

1. Imperfect sterilization of a new tube might lead to bacterial contamination of the solution in passage through it. This was rendered unlikely by the continuance of the reactions into the second day, after two half-hour sterilizations by boiling. Careful washing, rinsing and irrigation of the tube, filling with water before sterilization, and the fact that all glassware and other equipment in the experimental material and controls was subjected to the same treatment, made the possibility of bacterial accident even more remote.

2. Talc dust or some insoluble powder introduced into the circulation by the current passing through the

Fig. 1.—Two samples of "pure gum rubber" tubing: The lighter colored tubing (A) will give rise to reactions when new, if used for intravenous injection of arsphenamin and certain alkaline solutions; the darker tubing (B), even when new, apparently does not give rise to reaction.

* From the Section on Dermatology and Syphilology, Mayo Clinic.

tube might be the cause of the reaction. This was rendered unlikely because of the careful washing and rinsing to which tubes are always subjected, and further by the fact that a new tube produced reactions in every instance (six cases) even after a powerful stream of tap water had been forced through it for twelve hours.

3. A reduction in the alkalinity of the arsphenamin solution passing through the new tube, giving the effect of an injection of slightly acid arsphenamin, might be responsible for the reaction. To oppose this possibility it was found that normal sodium hydroxid solution titrated 98 per cent. normal after tubing had been soaked in it over night. The reduction in alkalinity in a rapid passage through the tube must therefore be within negligible limits, and would not be manifest after the first or second injection.

4. The toxic substance, a constituent of the rubber, might decompose arsphenamin, rendering the drug itself toxic.

5. The toxic substance might induce colloidal changes in the arsphenamin solution.

6. The toxic substance per se might be dissolved from the rubber and introduced into the circulation by the solution passing through the tube.

In interpreting our investigations, the fact should be emphasized that the same brand of arsphenamin was used from the beginning of our observations in 1918, and that we were thoroughly familiar with its behavior from experience in approximately 20,000 injections. Quantitative neutralizations, not visual end-point reactions, have been employed during the last eight months in the preparation of the solution. The sodium hydroxid was prepared for us by Kendall, and is standardized by titration and not by weight. The glass used was Pyrex or Jena, the water redistilled from glass, and the dilutions, rates, and conditions of administration closely approximated Public Health Service standards. Whenever comparisons between tubes were made, the conditions for both old and new tubes were kept identical. The tubing used by this service is sold as pure gum rubber tubing, and is manufactured by one of the largest and oldest rubber concerns in this country, so that the product probably is widely distributed over the United States. That a pure gum rubber tubing can be made which does not produce reactions, even when new, we ascertained in the course of our experiments (Fig. 1). About 80 cm. of tubing of an internal diameter of 4 mm. was employed in our work.

On further study of the reaction, these facts appeared:

1. Neo-arsphenamin, diluted 20 c.c. per decigram, as is our practice with arsphenamin, produced reactions

when given through a new tube exactly as in the case of arsphenamin and of the same intensity, in spite of the lower intrinsic toxicity of the drug (six cases).

2. Soaking washed and sterilized new tubing fifteen minutes in neutralized or slightly alkaline arsphenamin solution just before administration caused the arsphenamin solution to produce reaction even when given through an old, nonreacting tube (six cases).

3. Using sodium hydroxid in which new sterile tubing had been soaked twelve hours, to make up the fresh arsphenamin solution for administration, did not make the arsphenamin solution, thus prepared, toxic.

4. Soaking new sterile tubing in acid arsphenamin solution and then neutralizing with fresh normal sodium hydroxid did not give rise to reactions.

5. The scrapings and dust mechanically removable from the inside of new sterilized tubing, even when present in sufficient amounts to produce visible turbidity in the arsphenamin injected through an old tube, did not induce reaction.

6. New tubing can be rendered harmless and incapable of producing reaction by soaking for six hours in normal sodium hydroxid solution.

From these observations it is suggested that:

1. The toxic substance is present in new tubes in sufficient amount to produce reactions in the patients receiving the first ten to twenty-five injections of arsphenamin given through a new tube 80 cm. in length within a period of two days. The reactions become less severe the longer the tube is used.

2. The toxic principle is not destroyed by boiling for one hour, is not soluble in water, and is not contained in the washings and mechanically removable debris from the inside of new tubes.

3. The toxic substance dissolves in or acts on neo-arsphenamin and arsphenamin when these drugs are employed in a dilution of 1 dg. to 20 c.c. of redistilled water.

4. The solution of the toxic substance or its chemical action is so rapid that merely passing 50 c.c. of the injection fluid through a new tube in four minutes will produce enough effect to give rise to marked reaction.

5. The toxic principle is removable from new tubing by soaking it in normal sodium hydroxid solution for six hours.

In order to ascertain whether the toxic agent is soluble in sodium hydroxid solution in the concentra-

tion in which it enters into the neutralization of arsphenamin (45 c.c. of normal sodium hydroxid per 5 gm. of arsphenamin per liter of water), we prepared a solution of 45 c.c. of normal sodium hydroxid per liter of water and ourselves received each 50 c.c. intravenously through a new sterile tube, with ensuing vio-

Fig. 2.—Series of photographs illustrating "tubing reaction" in the dog: Top, both animals alert and in good condition before injection. Center, both animals one hour after intravenous injection of 50 c.c. of approximately 0.18 per cent. solution of sodium hydroxid; the black dog received his injection through a used piece of rubber tubing, the white dog through a new one; the white dog has had a chill and vomited, the black dog is unaffected. Bottom, tubing reaction at its height; high fever, severe diarrhea and cramps, vomiting and depression; the black dog (old tubing) had no reaction whatever; in ten hours the white dog had completely recovered.

lent reaction. The toxic principle is, therefore, present in the dilute sodium hydroxid solution passed through the tube, and can presumably be obtained thus for chemical study, although its stability in such solutions is not yet ascertained.

Striking success in our efforts to transfer the problem to animals has thus far been obtained in the case of dogs (Figs. 2 and 3). In them it has been shown that if the same dilute sodium hydroxid solution is given intravenously through an old tube to one dog, and through a new tube to another, the dog which receives it through the new tube reacts characteristically; the other shows no effect. If, a week later, the procedure is reversed, the reaction occurs in the dog

decreases. In from thirty minutes to an hour after injection, an increasing weakness, with aching of the legs and back, is noticed, followed by a chill, often of great severity (Fig. 4). The chill may be the first symptom. Nausea and vomiting occur with violent cramplike pains in the lumbar region, and diarrhea with tenesmus. Headache is intense, and with repetition of the rigor there is a sharp rise in temperature, the fever reaching from 102 to 103.5 F., accompanied by varying degrees of emotional disturbance, and prostration. The temperature (Fig. 5) then usually declines to normal within eight hours, but the fever may persist for two or three days, and the headache, backache, gastro-intestinal disturbance and prostration may per-

Fig. 3.—A, chart of tubing reaction in the dog following an intravenous injection of 50 c.c. of 0.18 per cent. sodium hydroxid solution given through a sterilized new "pure gum rubber" tube; note the chills, fever, vomiting, diarrhea, cramps and prostration characteristic of the reaction in man. B, chart of control dog, which received an equal dose of the same sodium hydroxid solution, but through a "pure gum rubber" tube that had been in use for some time; absolutely no reaction; solid line, temperature; broken line, pulse.

who receives the solution through the new tube, although by the use of an old tube this dog escaped reaction the week before. There is, therefore, no mere idiosyncrasy at the bottom of the reaction, and it is not due to the alkali alone. Efforts are now being made to transfer the problem to rabbits for greater facility in physiologic testing. The dog will apparently respond with somewhat less intensity than man to a dose of toxic solution about seven times as great per kilogram.

DESCRIPTION OF THE REACTION

The "tubing reaction," as we shall temporarily designate it for lack of a better name, presents a highly characteristic clinical picture when of maximum intensity, but graduations into atypical and mild forms appear as the toxicity of a given piece of tubing

sist for several days to a week. Both of us developed a profuse crop of herpes following the reaction. We have seen one case of jaundice, but no renal complications. Considering the extremely pronounced and unpleasant character of the symptoms, the recovery in robust persons is rapid and complete. It is conceivable that the reaction in the debilitated, or when coupled with a Jarisch-Herxheimer reaction or an intolerance of arspenamin, might have serious consequences. One of us (Busman) developed a leukocytosis of 14,600, with 94 per cent. polymorphonuclears at the height of the fever. The other (Stokes) had a white count of 5,600, with 92 per cent. polymorphonuclears. Both urines were normal. The pulse is likely to remain rapid for several days. Important symptoms may fail to appear or may assume unusual severity. The gen-

eral features of the reaction, however, run so true to form both in man and in the dog that they suggest the toxicologic action of a definite poison.

COMMENT

While the use of pure gum rubber in all tubing employed in arspenamin apparatus has been tradi-

suggests that this factor has been silently at work,¹ although to attribute the reactions described in any special reports to it, in the absence of data as to the tubing used, is only to indulge in speculation. Publication of our results may, however, stimulate further observation and serve, too, as a caution to those of us who are disposed to put the blame for every accident

Fig. 4.—Chart of the reaction of one of the authors to an intravenous injection of 50 c.c. of 0.18 per cent. of sodium hydroxid solution given through a sterilized new "pure gum rubber" tube; the other author likewise received the toxic solution and had an even more severe and typical reaction, with vomiting, diarrhea and tenesmus; solid line, temperature; broken line, pulse.

tional in our technic, a careful search of the literature from 1910 to the present time has thus far failed to disclose specific reference to or authority for our practice. While the familiar references to "Wasser Fehler," "Salz Fieber," and to the possibility of minute quantities of lead and silicates being responsible for the erratic behavior of arspenamin are common enough, we have been unable to find any evidence that the ingredients of rubber have been considered a potential cause of reaction in intravenous injection. From our study it is apparent, we believe, that even tubing marketed as of pure gum rubber may in the process of manufacture have acquired dangerously toxic properties, especially when used in the injection of alkaline solutions. That it is possible to make a gum tubing that has apparently no such toxic properties, and that soaking even toxic tubing in normal sodium hydroxid solution for six hours, followed by rinsing, removes the poisonous principle, points the way to a remedy. A review of the literature of arspenamin reaction certainly

on either the operator's technic or the drug. The identity and toxicologic action of the cause of the reactions described will be made the subject of further communications, including a consideration of possible relations to transfusion reactions when tubing is employed for the conduction of blood and other reagents.

CONCLUSIONS

1. A certain widely distributed brand of so-called pure gum rubber tubing seems to contain, when new, a toxic agent responsible for a definite type of reaction following the intravenous administration of arspenamin, and possibly also of alkaline solutions and transfusion mediums.

2. The toxic substance gradually disappears from the tubing on use.

3. The toxic substance is apparently removable in the first instance by soaking the tubing for six hours in normal sodium hydroxid solution and rinsing.

1. See, for example, the group of reactions reported by Guy at Camp Travis (J. A. M. A. 73: 901-904 [Sept. 20] 1919) in which the description of the reactions experienced by thirty-five patients in a single forenoon tallies in almost minute detail with the tubing reaction as we have observed it.

Fig. 5.—Charts of four patients who developed tubing reaction during their courses of treatment: Solid line, temperature; broken line, pulse.

4. The toxic property is not destroyed in the ordinary process of sterilization by boiling (from one-half to one hour), is not soluble in water or removable by irrigation, appears in toxic amounts in arsphenamin, neo-arsphenamin and dilute sodium hydroxid solution merely on passing them through a new tube en route from container to vein, and is not apparently associated with the mechanically removable debris from the inner surface of the tube.

5. The reaction induced by this agent, as obtained by the use of new tubing for intravenous injection of the substances mentioned, consists of chills coming on from thirty to sixty minutes after injection, with nausea, vomiting, diarrhea, a sharp rise of temperature, sweating, severe headache and lumbar cramps, emotional disturbance amounting at times almost to hysteria, and subsequent profound prostration.

6. The reaction can be induced in typical form in dogs.

7. The identity and toxicology of the poisonous principle are under investigation.

NONOPERATIVE DETERMINATION OF PATENCY OF FALLOPIAN TUBES IN STERILITY

INTRA-UTERINE INFLATION WITH OXYGEN, AND
PRODUCTION OF AN ARTIFICIAL
PNEUMOPERITONEUM

PRELIMINARY REPORT *

I. C. RUBIN, M.D.
NEW YORK

The value of oxygen in conjunction with the roentgen ray as an aid in the diagnosis of obscure abdominal conditions has been demonstrated in a number of recent publications. No ill effects have accompanied or followed the pneumoperitoneum produced by inflation of the abdominal cavity with oxygen gas. The tolerance of the peritoneum for oxygen even in large volume, and the fact that its presence can be detected by fluoroscopy and roentgenography have led to its use as a diagnostic procedure in determining patency of the fallopian tubes. If the gas injected into the uterus under certain measurable pressure would pass into the fallopian tubes, it ought to reach the general peritoneal cavity. In patients with patent fallopian tubes the gas would establish an artificial pneumoperitoneum identical with that produced when injected by direct abdominal puncture. In patients with occluded tubes no such result could be obtained.

Accordingly, experiments were carried out on extirpated uteri with the adnexa intact. In the first experiment it was readily seen that oxygen passed into the uterine opening of the tubes and then escaped through the fimbriated end. When the tubes were ligated or were occluded by pathologic processes, this did not follow. After determining the amount of gas required for our purposes, the first clinical application of the intra-uterine oxygen inflation was made, Nov. 3, 1919, at Mount Sinai Hospital. It was successful in proving the patency of the fallopian tubes in this first patient. The abdomen became visibly distended and the pneumoperitoneum was confirmed by the roentgeno-

graphic examination. The symptoms associating the gas inflation by way of the uterus were the same as those described for the method by direct abdominal puncture.

Encouraged by the result of the first trial, I tested it out in a series of thirty-five cases of sterility in which there were different clinical histories and physical findings. In this first series it was our endeavor to find out the limits of application, the quantity of gas to be employed, the time and rate of flow, and the reliability of the oxygen injected as a diagnostic procedure. In the second series of twenty cases, estimations were made on pressure. This has proved a valuable adjunct. Altogether, fifty-five patients were examined by means of oxygen inflation of the uterus. There were absolutely no untoward symptoms or sequelae. The patients with two exceptions were ambulatory, and were allowed to go home from within a few minutes to a half hour after examination. Two cases were from the hospital wards. The patients were all followed up and carefully examined for complications, none of which have to the present writing appeared.

In some cases the result confirmed our clinical diagnosis of probably closed or patent tubes. In a number of cases the tubes were proved to be open when we had reason to suspect they were closed by disease, while in others the tubes were demonstrated to be occluded when we had believed them to be normal. The method had practically the value of an exploratory laparotomy for purposes of determining the continuity of the lumen of the fallopian tubes. The two possible dangers, namely, embolism and infection, are more theoretical than actual.

Embolism from oxygen introduced into the uterus in a stream of discrete bubbles never occurs, and infection need never occur if the cases are not acute and are properly selected. In fifty-five cases which form the basis of this preliminary report, there were no symptoms even suggestive of a possible peritoneal irritation, although some of them had presented gross pathologic conditions before the examination was made. These questions, with the case histories, will be more fully discussed in a future communication.

261 Central Park West.

Children's Year: Looking Backward and Forward.—In thirty-eight states the Children's Year child welfare committees have planned to "carry on" with the cooperation of the Children's Bureau; in thirty states child hygiene divisions have been established, and in sixteen states child welfare commissions have been appointed. The end of Children's Year was marked by an international child welfare conference in Washington, at which minimum standards were drawn up, discussed in eight regional conferences throughout the country, and put into final form by an advisory committee formed for that purpose. These standards cover the fundamental needs of maternity and infant care; of the preschool and school child; of the child in need of special care; of the child at work; and of the economic and social bases for these standards. The standards for the protection of maternity and infancy are already crystallized in the Sheppard-Towner maternity bill now in Congress. This bill would make available to all mothers public health nurses, accessible hospital care and medical attention; consultation centers; teaching and practical demonstration in hygiene of maternity and infancy, and the household arts essential to the well-being of mother and child. One hundred and thirty-four children's health centers were established in fifteen states; in nine other states they were reported but the actual number not given.

GENERALIZED NEUROFIBROMATOSIS

WITH REPORT OF A CASE

LELAND H. ANDERSON, M.D.

WICHITA, KAN.

Generalized neurofibromatosis, as a special class of multiple neuromas, was first described by von Recklinghausen in 1882. It has since been called "von

as small, flattened, sessile tumors; long flattened pendulous taperings, or knobby, warty, gnarled formations. "Neuroma racemosum plexiforme," or "elephantiasis congenita" (Barker) are among the names applied to the condition. Often "rolling palpation" will detect numbers of the smaller swellings, too small to be seen on ordinary inspection, just below the skin surface. According to von Recklinghausen,¹ the tumors originate in the endoneurium of the nerve trunks in the subcutaneous tissue.

Etiologically, nothing is definitely known except the presence of a congenital predisposition. According to Osler, the tumors are believed to originate in the neurilemma (sheath of Schwann), because of the fact that the "olfactory and optic nerves, which are devoid of this sheath, have never been found affected with neurofibromatosis."² This is somewhat at variance with a statement by Barker³ to the effect that "it is this tumor that affects the nervus acusticus at the cerebellopontile angle; the nervus trigeminus is also frequently involved." Osler mentions the report of a case by Prudden, with nearly 1,200 tumors distributed on the nerves of the body, and says that "fibroma molluscum multiplex" is a term that has been applied to the peripheral cutaneous form of the disorder.

Ganglioneuromas, the true type of nerve cell tumor, contain and are largely made up of ganglion cells. They are largely confined to the sympathetic system and the chromaffin system, often in the region of the suprarenals. The tumors presented in this report, however, are largely those of connective tissue framework origin.

They have certain interesting and fairly characteristic findings. Persons affected have a peculiar tendency toward pigmentation of the skin, irregularly distributed, and much accentuated over those areas normally containing pigment cells. Nevus formations, both of the capillary and of the cavernous type, are common, and Harbitz⁴ considers them a feature of the disease. Neither pigment nor nevi seem to elect the mucosa of the oral cavity. Typical tumor groups are soft, velvety, semifluid masses, pinhead to pigeon egg in size, and feel to the palpating finger much like a soft, over-ripe, small grape. Below the skin surface, they are more often smooth, elongated swellings along the nerve trunks, easily detected by soft, uniform, gliding palpation with the palm. When evenly distributed, in considerable numbers, they give the affected

part a swollen, edematous appearance, wherefore, probably, the name "elephantiasis neuromatosa." Any portion of the nerve, from the ganglion cells of origin to the periphery, may be involved. The symptoms produced, therefore, depend more or less on the anatomic locations. These patients are prone to mental

Fig. 1.—Involvement of the right eye, with drawing of the mouth to the left, lagophthalmos, and collapse of the ala nasae.

Recklinghausen's disease." Pathologically, it is a type of fibroma, apparently taking origin from the connective tissue of the nerve strands. Nerve trunks, roots or individual peripheral nerve fibers may be involved; and different fibers of the same nerve, as well as derivatives of many different trunks in a given area, may exhibit lesions. The swellings may be near the skin surface, in the case of the peripheral nerves, or deeply buried in the tissues, and at any distance from the point of origin of the trunks. In shape they are often short and bulbous, or long, tapering and pyriform. Projecting above the plane of the skin surface, they appear

change, with loss of or weakened memory, both for recent and past events. Sometimes there is pronounced speech difficulty, caused, in all probability, by interference with innervation.

REPORT OF CASE

The patient whose pictures accompany this report is a woman about 38 years of age. She is mentally alert, but has an exceedingly poor recollection of events one or two days past. She is exceedingly irritable and hypersensitive, refusing any sort of examination except in a closed room. Trifles serve to throw her emotional nature into wild play, and at times she is much like a child of 4 or 5 years. She has some speech difficulty, though there is no demonstrable involvement of the recurrent laryngeal or superior laryngeal nerves.

According to her statement she was a normal child until about 6 years of age. At that time a small nodule appeared in the skin under the left mandible, grew rapidly for a time, and then stopped. It has now been far outdistanced by those appearing subsequently, but still remains the same size. There are now more than 3,000 various sized tumors on and below the skin surface, though the photographic details are insufficient to show the smallest ones, or those that lie just below the corium. The patient is one of five children, one brother having the same condition in much less degree. One paternal uncle is said to have had a similar affection. Otherwise the history is negative.

A number of representative tumors were subjected to microscopy, but no tissue that could be construed as of nervous or ganglion-cell origin was found. No frank evidence of malignancy or excessive proliferation was found, though some cell elements were suggestive of sarcomatous (as opposed to carcinomatous) change, being large and spindle shaped, with karyokinetic and double nuclear changes. The type cells were rather large, puffy, succulent fibroblasts, unstratified, but thin and elongated in the region of the pedicle. Unna's⁵ large mast cells were not found. Blood vessels were very few in number. The larger and presumably younger fibroblasts were grouped and bunched by numerous fibrous connective tissue septums, the whole surrounded by a sort of capsule quite separate and distinct from the overlying basement membrane of the epithelial surface. The intervening space was comfortably filled with an accumulation of fat cells, increasing at the base until only a very dense, thin fibrous connective tissue stalk penetrated the plane of the normal skin surface. These fibrous cords, in six instances, were followed below in the attempt to find their origin, but no definite conclusions could be reached, since they immediately spread out umbrella-wise, mingling with the fibers of the superficial white connective tissue fascia. The entire body surface was studded with these tumor masses: scalp, back, chest, abdomen, extremities and genitalia. Pictures of the latter were not obtainable though involvement was largely confined to the labia minora, which were excessively large and pigmented. The attempt to reproduce the chief involvement of the extremities, that of the right foot, was, for a time, futile. Strangely, she did not object to being photographed, front and back, thus illustrating what is meant by "mental eccentricity."

As is shown in the illustrations, there is a decided tendency toward grouping about the pigmented areolar areas of the breasts, where the protecting skin is disproportionately thickened, and a uniform trend toward pedunculation exists. A glance at the shoulder girdle, front and back, shows a number

of the small warty excrescences which are quite often found in persons, above the age of 40, of the dark skin, fatty, pigmented type. In those persons there are seldom more than three or four tumors; but the question may be raised as to whether or not many more of these than are diagnosed are really mild fibromatoses. The diagnosis is readily made in the presence of many tumor nodules, but is this a prerequisite to the diagnosis? It must be admitted that the "feel" of the occasional and scattered nodules is quite different from that of the well developed cases, but it is probable that the incidence of early fibromatoses is higher than commonly it is supposed to be, since there is a factor of self limitation in their growth.

Along the margin of the right scapula is a mass the size of a hickory-nut, heavily pigmented and consisting almost entirely

Fig. 2.—Involvement of the skin of the back.

of a cavernous angioma. The profusions of vessels here, contrasted with their scarcity in most of the other masses, raises the question as to whether they are of the same type in different stages, or entirely different and coincidentally developing types.

Usually this patient is not inconvenienced in any way except by the mental anxiety. Sudden temperature changes, however, produce tingling, and a feeling of tenseness and swelling in the nodules. Sudden mental stress, anxiety or anger produces the same result.

There is no evidence of intracranial pressure. The right olfactory, optic, oculomotor, trigeminus, facial, and the cochlear branch of the eighth cranial nerves, however, appear to be involved.

A wide variety of distinctive odors was readily recognized without hesitation, but thorough cocaineization of the mucosa

5. Unna: *Histopathology*, p. 847, quoted by Ormsby, O. S.: *Diseases of the Skin*, Philadelphia, Lea and Febiger, 1915, p. 601.

of the left nostril high up produced much confusion, on several occasions, leading to complete errors in identifying substances formerly very familiar.

Perception of light remains only on the right side, dating from the age of 6, or thereabouts, and coincident with the development of the first tumor masses remembered. At that time the right visual field began to diminish steadily, until in a short time only the present amount of vision remained. The left fundus and visual field are normal. The right fundus shows merely a small, pale, atrophic disk. There is no edema or change in the retinal vessels. No change in the intensity of a point of artificial illumination is perceived by either the right or the left half of the right retina, suggesting a lesion anterior to the optic decussation. Coordination of the ocular bulbs is markedly disturbed, and while the right external rectus and superior oblique retain practically their full power (the fourth and sixth nerves), the remaining extrinsic eye muscles (the third nerve) are quite unbalanced; the eye rolls aimlessly, and on attempt at forcible closure of the lid, deviates out and upward (Bell's phenomenon). The bulb is considerably proptosed. The upper lid hangs loose and flaccid over it, and cannot voluntarily be raised. The lower lid is in mild ectropion. The drooping of the upper lid was first noted a year after the initial disturbance of vision on the same side, and has gradually increased. The right pupil is widely dilated, very slow both to light and accommodation, and does not exhibit the consensual reaction. Therefore a paresis of the third nerve is suggested.

The patient is unable to elevate the frontalis muscle, which speaks for a peripheral lesion of the seventh nerve (Bell's paralysis), since in central lesions of this nerve the power of the frontalis muscle is largely retained. The nostril of the same side is patently collapsed. Taste, however, is undisturbed over the entire tongue, and the right submaxillary and sublingual glands secrete normally, and respond to atropin, suggesting that the chorda tympani is undisturbed by the lesion affecting the seventh nerve.

About two years after the initial disturbance of vision, the right side of the face became softened and "looser"; the buccal wall was occasionally bitten, and food collected in the cheek pouch, suggesting involvement of the buccinator nerve (a branch of the third division of the trigeminus) as well as the facial nerve. The mouth is drawn somewhat more to the left than appears in the illustrations, and the right eye could not be forcibly closed, thus indicating a seventh nerve lesion. The area served by the sensory portions of the maxillary and mandibular divisions of the trigeminus is now relatively insensible, except to extreme degrees of stimulation. The area of the ophthalmic division of the trigeminus appears normal, since the lacrimal glands of the right side secrete normally and respond to atropin, and the areas of distribution of the frontal and supra-orbital nerves (branches of the ophthalmic nerve) are sensitive to ordinary stimuli.

More than a year after the trouble with the face came the first intimation that the patient was becoming deaf in the right

ear. According to her statement, no increase of deafness has been noted since that time, although such belief is not based on any accurate tests. The type of the present deafness is that

SOUND CONDUCTING AND PERCEIVING

Test	Right	Left
Rinné.....	+ (Bone < normal)	+ (Bone = normal)
Weber.....
Dench.....	+ (-5 seconds)	+ (-3 seconds)
C.....	+ (-18 seconds)	+ (-3 seconds)
Voice (moderate low).....	32 feet	44 feet
Acoumeter.....	2 feet	41 feet, 4 inches

for high tones. Sounds in the moderate wave lengths are detected with little difficulty, provided attention is concentrated on them. There is reason to believe that even in the moderate amplitudes, tone "islands" are present; but extended detailed examination was refused. The accompanying table gives the results of the sound-conducting and sound-perceiving apparatus. The minus quantities, in parentheses, signify that time below the normal ear. All timing and distance measurement is accurate. A combined deafness of the right side is of course suggested, but the great preponderance is on the side of the nerve.

So far as can be determined, the vestibular portions of the eighth nerve and its connecting tracts are normal. Normal falling, vertigo and past-pointing result from both the stimulation of turning, and douching. The right nystagmus is very confusing because of lack of control of the extrinsic muscles, the rolling of the bulb making decisions regarding nystagmus unsatisfactory and contradictory.

Figures 3 and 4 are views of the right foot, which is the most extensively involved of any of the extremities. The fourth toe is lost in the maze of redundant tissues, although the phalanges are readily palpable, and appear normal on the

Fig. 3.—Enormous tumor mass on the right foot.

roentgenogram. The thick pad on the sole is devoid of the sensation of pain, except that deep pressure produces a dull ache. Other sensations are normal. The skin is soft, thin and but little calloused, while the mass feels much like a large varicocele. The patient states that the malformed portion of the foot seldom sweats. Except for the mechanical inconvenience in walking, no discomfort is experienced. All reflexes and sensory tests on both feet are normal.

There is nothing in the general physical examination to suggest involvement of the cord tracts or the peripheral spinal nerves. Proctoscopic examination in search of the rectal tumors described by Cooke⁶ reveals nothing of importance. The blood and spinal fluid Wassermann tests, after provocative treatment, are negative. The gold chlorid curve shows nothing suggestive at either end of the scale. The general deep and superficial reflexes are neither sluggish nor exaggerated. No atrophy, fibrillary twitching, paresis, trophic changes or reaction of degeneration could be demonstrated.

6. Cooke: *Am. Med.*, Nov. 21, 1903, p. 818.

COMMENT

Allowing proper latitude for a history, in its bearing on a relatively remote period, it would seem that the involvement of the cranial nerves began early, and first with those lying anteriorly. The fourth, motor fifth (portio minor), sixth, vestibular eighth, tenth, eleventh and twelfth cranial nerves appear untouched. According to Bassoe and Nuzum,⁷ "the fifth and eighth cranial nerves are those most frequently involved within the skull, but when we include all the peripheral nerves the order of frequency seems to be: vagus, abdominal sympathetic, sciatic." In this case none of this triad could be proved abnormal. The involvement of the right side has been apparently regular, successive, and to a degree, at least, self limited. Repeated efforts to implicate the hypophysis in connection with the eye disturbance, by means of functional tests and gland feeding, proved unsuccessful. There are, moreover, no skeletal or soft tissue stigmas or other signs of any endocrine dyscrasia.

In the absence of necropsy, not many deductions are justified. However, "it may be recalled that, unlike all the other cranial and spinal nerves, the optic and olfactory are devoid of the sheaths of Schwann, and of the cells giving origin to the same."⁸ If the involvement of the first and second cranial nerves in this patient is due to the same type of tissue change seen on the external surface, it would seem that the sheath of Schwann plays a part of immensely minor importance in the etiology of the disease. This brings up the question of tuberous sclerosis, which is beyond the scope of the report.

Mothers' Pensions—According to a bulletin entitled "Laws Relating to Mothers' Pensions," just issued by the Children's Bureau of the U. S. Department of Labor, thirty-nine states, Alaska and Hawaii now have some public provision for mothers left with young children to support, and in at least five of the remaining states, mothers' pension laws have been under consideration. Canada, Denmark and New Zealand also have passed legislation providing aid for mothers. Generally speaking, all mothers' pension laws provide for the payment of a stated weekly or monthly sum for each child under a certain age to mothers who are dependent on their own efforts to support their children, and are morally and physically fit persons to bring up their children. There is considerable variation in the laws in force in the different states. Some states provide pensions only for widowed mothers; others include women who are divorced or who may have been deserted by their husbands, or those whose husbands are in prison, in state asylums, or who are otherwise incapacitated.

OXYGEN INFLATION OF THE PERITONEAL CAVITY

A PERSONAL EXPERIENCE

ARMITAGE WHITMAN, M.D.

NEW YORK

In an article by Stein and Stewart¹ on the roentgen examination of the abdominal organs following oxygen inflation of the peritoneal cavity, the roentgenograms were sufficiently beautiful to justify the moderate claims for the method as an aid to diagnosis in obscure abdominal conditions. The article referred to its employment in some eighty cases, and the bibliography embraced a number more. The authors' series of cases furnishes apparently the only instances of the deliberate employment of the method for diagnosis only, the other articles referring to its more or less casual use after laparotomies, paracenteses, and as a therapeutic agent in tuberculous peritonitis. However, the results of its use were in all cases at least innocuous.

It at once occurred to me that the method described offered a brilliant opportunity for a demonstration of the effect of posture on the internal organs. It is known in some circles, and halfheartedly admitted in others, that posture has a definite effect on the position of the liver, kidneys, colon, etc. Almost any one will grant that a person standing in a slouchy attitude, with the chest flat, back hollow, and abdomen prominent, is more likely to suffer from floating kidney or intestinal stasis, for example, than one who stands erect, aerates his lungs, and gives his viscera at least a modicum of outside support. In reality, however, such a patient stands small chance of this theory being put into practice until the appendix has been removed, the

Fig. 4.—Enormous tumor mass on the right foot.

floating kidney anchored, and possibly the mesentery plicated. If the patient is a woman, the operative possibilities are still more fascinating.

Abdominal palpation is unsatisfactory and almost impossible in the erect position, besides being a means far too susceptible to individual prejudice and variation. If we might show, however, a roentgenogram of the liver forced well up against the diaphragm, and the spleen and the kidneys back in their respective beds, all brought about by a change in the erect attitude, the demonstration would be as nearly final as one could ask. I therefore determined to make the first experiment of a series on myself, as I was confident of my ability to assume the desired attitude. I inquired from Dr. Stewart as to the possible disagreeable effects

1. Stein, Arthur, and Stewart, W. H.: *Ann. Surg.* 70: 95 (July) 1919.

of the injection on the patient, and was told that it naturally produced a sensation of distention and occasionally some pain between the shoulders, but that these symptoms never lasted more than twelve hours, or over night, and indeed were usually confined to the aged and very nervous. It was his routine to give one eighth grain of morphin about an hour previous to the injection. The quantity of oxygen was no longer measured by the rubber bag, but was injected directly from the tank. The pictures might be taken within a few minutes, allowing time only for the sufficient dispersion of the gas about the abdomen. The bowels were evacuated in the morning, the usual breakfast and practically no lunch being taken.

Dr. W. F. Cunningham kindly consented to make the injection for me. The point selected was at the outer margin of the left rectus muscle, about one inch below the level of the umbilicus. No preliminary morphin was given. The skin and fascia were infiltrated with 1 per cent. cocain hydrochlorid. A No. 16 trocar and cannula was then introduced through a minute skin incision. No pain whatever was felt from the passage of the trocar. The trocar was withdrawn and the cannula connected with a rubber tube leading from a bottle of hot sterile water, which was in turn connected with the oxygen tank. The tank was then turned on and the oxygen allowed to flow slowly through the warm water into the peritoneal cavity. There was no sensation at first. After two or three minutes, bubbles could be felt gurgling about. After ten minutes, liver and splenic dulness was obliterated, and a fairly marked sense of distention became apparent. Turning slightly from side to side seemed to facilitate the dispersion of the gas. In about fifteen minutes a dull, aching pain began between the shoulders, and the injection was discontinued. At this time the abdomen, from having been almost scaphoid, was no more than flat. There was no appearance of distention. It was tympanitic all over, the lumbar gutters being the last regions to become so. Splashing and gurglings were apparent on auscultation. There was no alteration in respiration or pulse rate, which remained at 72. The blood pressure was not recorded. The first roentgenogram was taken in the supine position on the operating table, and seemed to show a fairly uniform dispersion of the gas, not however, as clearly as had been expected.

I then stood up. Rising was performed slowly and with assistance and was no more than uncomfortable. Anteroposterior roentgenograms were taken in the slouchy and the erect attitudes, and immediately afterward photographs were taken in the same attitudes, to accompany the roentgenograms and to contrast with the same poses taken before the injection. Taking the pictures did not require more than ten minutes, during which time I was conscious of increasing epigastric distention and discomfort, which made me anxious to lie down while the roentgenograms were developed. They were not as satisfactory as had been hoped, so that I stood up again to have a second series taken. The act of rising this time was much more uncomfortable, and I was conscious that the discomfort was increasing. While getting my clothes on and walking to the door, I found myself walking and holding myself with extreme care to avoid any jar.

As home was near by, it seemed as well to go there and lie down as to stay indefinitely in the hospital. When I came outdoors, the discomfort at once became much greater. The chest was held in midexpansion, and the breath was held as long as possible and expelled with a grunt. Inspiration was shallow, and the thoracic walls were held as rigid as could be, apparently in the effort to restrict the movements of the diaphragm. After I had walked one block very slowly the discomfort had become a pain, and the apprehension of being jarred or bumped had become extreme. It was literally fear lest a collision or decided jar would cause something to burst. The pain between the shoulders was increasingly severe. When home was reached, lying down at once gave great relief. The respiratory embarrassment disappeared. The sense of abdominal distention and oppression in the epigastrium remained. Four hours after the time of injection it was possible to sit up and eat a light supper. Any movement, however, was made with extreme care, and a resumption of the erect attitude for any time caused a recurrence of the pressure on the diaphragm. Except for discomfort on turning, sleep was not interfered with.

Fig. 1.—The slouchy attitude.

The following morning I woke comfortable; but when I moved, the abdominal cramp at once returned. Dressing was attended with much discomfort, bending over to lace the shoes in particular being almost impossible. In going out to walk three blocks to the office, I at once felt very acute discomfort. It was impossible to walk at even a reasonable rate. The apprehension of a jar returned, and a new symptom appeared, extreme pain referred, as nearly as I can describe it, to the heads of both humeri, worse as a rule on the right side. I was never able to decide whether or not that particular pain was caused by the cold air or the added exertion of walking on the street. It was not caused by the usual degree of activity about the house. Standing and sitting in the ordinary position were excessively uncomfortable. Reclining in a Morris chair gave considerable relief, and while I remained quiet in that position, there was simply a constant sense of epigastric oppression. I could not appreciate any diminution in the volume of gas.

For ninety-six hours after the injection, these symptoms remained practically constant. Becoming as time wore on more familiar with the gas, and therefore more contemptuous of accidents, I finally discovered what could give relief. The most effective remedy for the continuous epigastric oppression was standing on the head. After a few seconds in that position the gas could be felt escaping from the subdiaphragmatic space and gurgling up into the true pelvis. Respiration then became at once easy, and the cramped sensation and abdominal distress disappeared. If I could then be lowered to the horizontal, and pillows placed under the sacrum to hold the lower quadrants higher than the upper, the relief might persist for some fifteen minutes. Any change of position, however, released the gas, and the pressure on the diaphragm recurred. Urination was not affected. Defecation became more frequent, three movements a day being the average, loose in character, accompanied by considerable gas. Movements were followed by slight and temporary relief. It may be of interest to note

that it was impossible to distinguish by sensation between gas within and gas without the intestine. Appetite was increased, but probably because its satisfaction produced so much discomfort as to make a full meal inadvisable. There were, however, two or three sudden attacks of hunger, very much like the hunger pain of chronic dyspepsia, which were relieved by a few crackers and a glass of milk. The pulse rate was never appreciably altered. Respiration was increased by exposure to cold and exertion. There was no evident change in color from oxygen absorption.

The gas was absorbed—or at least the symptoms of its pressure disappeared—quite suddenly on the fourth day after the injection. Gas bubbles could still be felt on the fifth and sixth days, but their presence was not sufficient to cause noticeable symptoms. During the first four days I should have been grateful for the opportunity to spend my entire time in bed. Short of being totally incapacitated, I have never undergone such an uncomfortable, painful and thoroughly disagreeable experience.

I am putting this experience on record not because I wish to discourage the employment of the method, the importance of which has been already demonstrated, but because I can find nothing in the literature that might lead one to take into account the sensations of the patient.

I ascribe the wide variance between my own and the average experience to the fact that I was not, either before or after, a bed patient. I assume that the average subject is in a hospital for diagnosis, and that the oxygen injection is only one of a number of procedures, between and during which the patients are in bed or at least on their backs. Also a number of the previous experiments cited had been of a different nature—the oxygen having been injected after operation, after removal of a tumor or of fluid from the abdomen—when it was employed purposely to avoid too sudden a change in intra-abdominal pressure. Manifestly this would modify the severity of the subsequent symptoms. I cannot see that immediately getting up and walking about could have been responsible for their increased severity and prolongation, as they were relieved at once by lying flat or standing on the head. The effect was evidently, then, purely mechanical, and one would suppose that activity and constant shifting of position would promote rather than delay the absorption of the gas. The accompanying illustrations will show that the amount of gas employed was not excessive, and certainly produced no undue amount of distention.

CONCLUSIONS

The experiment was a failure in regard to the purpose for which it was undertaken. In the erect position, the gas once having risen to the subdiaphragmatic spaces, it was impossible to exert sufficient pressure from below to force the liver up and squeeze the gas out. Contraction of the abdominal muscles from below upward also primarily reduced the space into which the gas could escape.

2. The actual injection of the gas was practically painless, and its presence in the peritoneal cavity was attended by none but mechanical disturbances incident to its physical volume.

3. These mechanical disturbances were of such an unpleasant and disabling nature that the method

should not be employed without their due consideration. The patients should be warned of what they might reasonably have to expect, and be prepared to spend from three to four days in bed following the injection. In nervous individuals the consequences might be considerably more disturbing.

"ANTIPLASMA" *

C. C. BASS, M.D.

NEW ORLEANS

A so-called specific cure for malaria called "Antiplasma," made by the Malarial Specific Company of New York, was recently investigated by the Propaganda for Reform department of THE JOURNAL.¹ The ridiculousness of the claims were noted and the composition of the nostrum as determined by the A. M. A. Chemical Laboratory was exposed.

Under ordinary circumstances such a "remedy" would not warrant further notice: perhaps not even that already given. Since the stuff is being extensively sampled and in some instances, at least, sold under the most extravagant claims to physicians, druggists and others in some of the Southern states, further information about it may be useful.

Feb. 19, 1920, the "southern representative" of the Malarial Specific Company brought a boy to see me who had just finished taking the third course of treatment with this "specific cure." His blood had been examined before and during the treatment and found to contain malaria plasmodia by Dr. F. M. Johns. I took a specimen of his blood, examined it, and found many malaria plasmodia, some of which were shown to the representative of the company. The explanation then offered for this failure to cure was that in the first two courses of treatment a preparation made by the wrong formula was used, and the last time he took the medicine only six days instead of seven, as the directions on the bottle advise.

Feb. 13, 1920, Dr. R. D. Dedwylder, Ruleville, Miss., put two men, in whose blood malaria plasmodia were found, on the "Antiplasma" treatment. The treatment was completed according to the "direction on the bottle," and on February 21, blood specimens were again collected. In the meantime, one of the patients had a clinical attack of chills and fever on the fifth day of treatment. I have examined the blood of both of these patients, taken February 21, after completing the treatment. Each contains many malaria plasmodia.

It so happens that the patient seen in New Orleans had estivo-autumnal plasmodia; one of those in Ruleville had tertian and the other quartan. We have in these three cases a fair trial of the "cure" in one case each of estivo-autumnal, tertian and quartan malaria, with 100 per cent. of failures. The use of this product to the neglect of the absolute specific for malaria, quinin, will contribute to the continuation of the disease in those who have it, and to spread of the disease to others.

* From the Department of Experimental Medicine, Tulane University of Louisiana School of Medicine.

Clinical Notes, Suggestions, and New Instruments

REPAIR OF CRANIAL DEFECT BY NEW METHOD

REPORT OF APPARENTLY SUCCESSFUL CASE *

GEORGE NOBLE KREIOER, A.M., M.D., SPRINGFIELD, ILL.

History.—J. W. W., boy, aged 4 years and 5 months, residing near Bates, Ill., accompanied his grandfather, about 2 p. m., Nov. 18, 1919, to the barn lot where there were several horses. When the grandfather opened a gate, one of the horses ran out, and in passing kicked the child forcibly over the left eye. He was immediately taken to the house, where the head was washed off.

Dr. J. C. McMillan of New Berlin, Ill., was called. Recognizing the serious character of the injury, he applied a sterile gauze dressing and took the child at once to the Springfield Hospital, where he arrived about 4:30 p. m. There was immediate consultation.

Examination.—There was a lozenge shaped compound fracture; the fissure in the bone was about 3 inches long, and 1 inch broad, running down at each end to a point. It began near the outer border of the superciliary ridge and passed upward and backward over the frontal prominence nearly to the median line. Two large pieces of bone were indriven, causing loss of considerable brain substance.

Treatment and Results.—Under ether anesthesia, about six pieces of bone were removed. The two large fragments were inserted in a pocket, which was prepared in the left hypochondriac region, and was made by a slightly curved incision, nearly 3 inches long. The tissues were separated by artery forceps and scissors. The two pieces of skull bone were completely buried, and the incision was closed.

The wound in the frontal region was thoroughly cleansed, a pledget of iodoform gauze was inserted in the cavity, and the edges of the wound were brought together, except at the ends.

Because of the circumstances under which the wound was received, a good sized dose of tetanus antitoxin was administered subcutaneously.

There was considerable oozing from the head wound, and slight fever; also, for a few days, edema of the left eye; otherwise the progress of the case was satisfactory.

November 29, under ether, the iodoform gauze was removed, and the edges of the wound were trimmed and brought closely together. The head was again thoroughly cleansed and permanent dressing was applied.

December 31, pulsation was visible and palpable where the bone was lacking. The scalp wound was solid except at one end where the mother had bumped it in putting the child on a chair at the dinner table. Final operation was deferred one week until this had healed.

Jan. 7, 1920, at 2 p. m., assisted by Drs. C. W. East and J. C. McMillan, I made a horseshoe shaped incision beginning one-half inch from the outer edge and to the left of the

original wound, and extending to one-half inch beyond the inner edge of the wound, or about the median line. The scalp was laid back toward the eyebrow, beyond the defect in the cranium. The dura was found firm and solid, closing off the brain. The edges of the dura were lightly dissected. The two fragments of bone were taken from the pocket and placed exactly in their former positions. A considerable layer of fat had become fastened to the outer side of these bones during their sojourn in the abdominal wall, and this was utilized in sewing them in place with fine catgut. The large scalp flap was then brought over, completely closed with silkworm gut, and a firm dressing applied.

January 14, the dressing was removed from the head for the first time. The new incision, which had been closed by silkworm sutures, was found to be perfectly dry. The line of first injury showed a pin hole opening at two points. There was a slight serous exudate, no pus was apparent, no pulsation was apparent and the bones seemed to be in good position and adherent. The abdominal wound was perfectly healed.

January 26, the wound was dressed and the bone appeared firmly fixed.

COMMENT

Three points should be particularly emphasized:

1. The implants should be placed in the hypochondrium with the outer surface of the bones in contact with the fatty tissues in this region. When they are removed, as much of this fatty tissue as possibly should be brought out with the bones. When they are replaced, this tissue should be sewed with fine catgut to the epicranial aponeurosis and the implants secured in place.

2. Some writers seem to think it quite necessary to dissect the dura away from the edges of the defect so as to bring its exposed outer surface on a level with the inner table of the skull. This was not done in my case. Unless there is good reason for this extensive, and possibly useless, dissection it should not be attempted. Even though a slight protuberance may exist, it is better than a defect. The cranial cavity is firmly and hermetically sealed, which is the important point.

3. A new flap was made to expose the defect. When the implants were put in place and enclosed, as I have indicated, this new flap exerted a certain amount of pressure, and finally will depress the dura to its normal position.

CONCLUSION

Usually, by implantation, it is possible to preserve the fragments of cranial bones for reimplantation when the original wound is in proper condition. The result in this case has been perfect recovery.

A SIMPLE METHOD OF DISTINGUISHING WHITE FROM RED CELLS IN SPINAL FLUID CELL COUNTS

S. R. GIFFORD, M.D., OMAHA

While laboratory men who are looking at spinal fluids every day have no difficulty in quickly distinguishing between these cells without staining, clinicians of less experience will often find a differentiation troublesome, even with the high power. The use of acetic acid or Turk's solution has the obvious disadvantage of further diluting what may be a fluid of low cell count.

I have found no convenient method in the textbooks on clinical diagnosis, and the following procedure which, from its simplicity, is probably being used independently by many men, I have not seen described:

The fluid is taken in two test tubes. To one of these, containing about 2 c.c., is at once added one drop of Loeffler's methylene blue, and the tube shaken gently. The second tube is saved for other tests. Examination after two minutes

Fig. 2. — Implants of skull, approximate size.

* Patient presented to the Sangamon County Medical Society, Feb. 9, 1920.

reveals the nuclei of the white cells staining distinctly, so that they may be easily distinguished from red cells by low power, and lymphocytes from polymorphonuclears by high power. If the stain is not acting quickly, two or three more minutes may be required, but never long enough for coagulation to affect results appreciably, except in a very heavy, turbid fluid.

COMBINED SCLEROSIS DUE TO ANEMIA OF THE

PERNICIOUS TYPE: REPORT OF CASE

FRANK H. REDWOOD, M.D., NORFOLK, VA.

History.—Miss M. A., aged 48, a suit saleswoman, whose family history was unimportant except that a maternal aunt had died of tuberculosis, and whose habits were good, noticed, in April, 1919, that her feet burned constantly during the day and that she felt tired. Two weeks later she had a sense of numbness in both feet, and in the legs as far as the waist, and had some difficulty in walking. When I first saw the patient, September 12, she was confined to bed because she said she could not walk alone. She complained of numbness in the lower limbs, slight nausea for the preceding two days, constipation, and a severe pain in the lumbar region and legs whenever she moved. She said she had a sensation of something's turning over in the abdomen.

Physical Examination.—The patient was a well nourished, somewhat obese woman. She lay quietly in bed; when I attempted to examine her she cried out with pain; but when her attention was attracted she could be examined without difficulty. The muscles were flabby. The heart was normal, the pulse was 75 in the recumbent posture and 80 when the patient sat up. The systolic blood pressure was 120 and the diastolic, 70. The teeth were in poor dental repair, and several were suspected of being abscessed. The thyroid was not enlarged, the skin was rather dry, the tongue was slightly red, and the throat was normal. The chest and abdomen were negative.

Neurologic Examination.—The gait was paraplegic and spastic, the station was unsteady but there was not a true Romberg sign. All deep reflexes were quite lively, but equal on the two sides. The superficial reflexes were not elicited; but this was thought at the time to be due to a fat, loose abdominal wall. There were no ankle or patella clonus, no Babinski, Oppenheim, Chaddock, Gordon or Hoffmann sign, and no Kernig sign. There was no astereognosis or adiadokocinesia. There was slight ataxia in the finger-nose test. All four extremities showed marked weakness. The pupils were normal in every way, as were the fundi. The cranial nerves were normal. The lower limbs showed small areas of analgesia or, rather, a delayed pain sense.

Sphincter control was normal. Roentgenograms of the teeth disclosed four that were badly abscessed. The urine was normal, the blood Wassermann was negative, the spinal fluid was clear; there were 100 cells, but the globulin and Wassermann tests were negative. With the exception of 78 per cent. hemoglobin, the blood count was normal. Examination of the stools and the stomach contents was not made.

Clinical Course.—During October and November, the patient improved somewhat, and on repeated examinations the physical signs remained the same. During a period of twelve days in the latter part of November, I did not see her. December 2, I was called to the house and was amazed to find the patient in a serious condition. She was acutely ill, the skin was sallow or lemon colored, the mouth dry and parched and the tongue, sore. All deep and superficial reflexes were absent, and there was a Babinski reflex on the right side. Deep muscle sense was lost. There was an easily exhaustible ankle clonus. The patient had absolutely no control over the rectal or vesical sphincter. The blood count revealed hemoglobin, 72 per cent.; red cells, 3,280,000; white cells, 7,600. The differential blood count revealed polymorphonuclears, 71.5; small lymphocytes, 18; large lymphocytes, 4.5; transitionals, 5, and eosinophils, 1. The red cells showed a few nuclear bodies, anisocytosis and poikilocytosis. Two days later, red cells were 2,300,000, white cells 14,000,

and hemoglobin 68 per cent. The patient grew rapidly worse and died, December 5. Necropsy was refused.

COMMENT

Degenerative changes of the cord in pernicious anemia are quite common, but cases in which symptoms are referable to the cord are comparatively rare. This case is reported chiefly on account of the difficulty of a diagnosis before the rather sudden change in the physical findings. At the first examination, the blood picture was practically normal, the deep reflexes were increased, and there were no pathologic reflexes and no sphincter disturbances. Eight days before death, the blood picture was that of atypical pernicious anemia, the deep and superficial reflexes were absent, there was a Babinski reflex on the right side, and the patient had no control of the sphincters.

310 Taylor Building.

A CASE OF HUMAN ANTHRAX*

GERALD R. ALLABEN, S.B., M.D., BUHL, MINN.

Anthrax in man is still uncommon enough to warrant the report of a case.

History.—W. I. L., man, aged 18, Finn, clerk in a mining office, noticed a small nodule on the left side of the neck just below the ear. Swelling of the neck began immediately. The following day, he consulted the physician at the mine, and hot compresses were applied. Twenty-four hours later, when next seen by the physician, the symptoms had progressed rapidly, and the patient was brought to the hospital. He had a temperature of 104 F.; pulse, 130, and respiration, 28. There was extreme swelling of the neck and face extending around to the right side and down to the left breast, and marked edema of the throat involving the uvula. Breathing was embarrassed and noisy, and there was great difficulty in swallowing. The patient complained of no pain except the discomfort from the edema. Blood count revealed 26,000 leukocytes. The urine was negative. The lesion was about the size of a nickel, and distinctly firm and indurated; the edges were raised and dotted with small vesicles containing a clear yellow serum. The center of the nodule was depressed, dark and necrotic. Smears showed anthrax bacilli, some specimens showing the characteristic spore formation.

Operation and Results.—Under local anesthesia the nodule was thoroughly excised, the base was cauterized with 95 per cent. phenol (carbolic acid), and the surrounding subcutaneous tissues were injected with 5 per cent. phenol. A dressing of 95 per cent. alcohol was then applied. Cauterization was repeated twenty-four hours later, and alcohol dressings were continued. The patient's condition did not improve, however. The edema remained unchanged. The patient became restless and noisy; the temperature remained high, reaching 105 at the last; the pulse grew weak and more rapid; leukocytes increased to 42,000; and death took place just forty-eight hours after admission to the hospital, and four days from the onset of the infection.

Comment.—A specimen of blood, sent to the laboratories of the state board of health at St. Paul for culture was reported free from anthrax organisms. It would rather be expected that a positive culture would be obtained in such a malignant case, and with the degree of leukocytosis that was present. The treatment in this case, aside from the management of the local condition, was largely supportive. An attempt was made to secure antianthrax serum for administration, but it did not arrive in time. It is more than probable, however, that the serum would have had no effect on the course of the disease. It seems likely that a new shaving brush was the cause of the infection, as has been demonstrated in many of the cases occurring in the army cantonments. This patient had bought a new brush one week before, and had used it only twice, the last time being the night before the appearance of the nodule on his neck. The brush was secured, and sent away for culture, but was apparently destroyed without examination.

ACETYSALICYLIC ACID (ASPIRIN) AND HEAT REGULATION

How largely the use of drugs is still based on empiric experience is now and then emphasized anew when scientific investigation directs its attention to the real mechanism of their action. This paucity of accurate information regarding the precise mode of action of many commonly used therapeutic agents is illustrated in the case of acetylsalicylic acid (aspirin). The drug is employed daily in medical practice, and has already attained the undesirable popularity of becoming a "household remedy" exploited daily in the public press and on the billboards. If a conscientious student of medicine were to have inquired only a few months ago regarding the details of the antipyretic manifestations of acetylsalicylic acid, his commendable inquisitiveness could not readily have been rewarded with accurate information. This is not due to the novelty in the use of acetylsalicylic acid, for the compound was introduced into therapeutics more than twenty years ago.¹

Thanks to investigations conducted by Barbour² in the Department of Pharmacology of the Yale School of Medicine, its action on heat regulation has been somewhat elucidated. Unexpected is the unlike behavior exhibited by normal, in contrast with febrile persons toward the drug. In the former, a dose of 1 gm. or more of acetylsalicylic acid produced no significant difference whatever in the output of heat. This absence of augmented heat dissipation was observed despite the fact that the drug was evidently pharmacologically active, as shown by an obvious mild stimulation of the total metabolism by therapeutic doses in the majority of normal persons. Barbour believes that there is probably no change in the nature of the materials burned, for the results as a whole indicate that the drug, in this dosage, does not alter the respiratory quotient. Any tendency for the body temperature to fall is probably compensated for by the

slight increase in heat production in the normal organism.

The observations on febrile persons, on the other hand, tell a different story. Acetylsalicylic acid, in 1 gm. doses, which have no such action in normal persons, exhibits a marked antipyretic effect in febrile, temporarily afebrile and convalescent subjects. Like other antipyretic drugs, it exerts its temperature-reducing action essentially by increasing the process of heat elimination. Barbour notes that although stimulation of the metabolism is not seen, as in health, there is at least no depression at all comparable in extent to the increase in heat dissipation.

Along with the altered heat regulation there is a tendency toward a decrease in the pulse rate. Temporary cardiac disturbances have incidentally been noted—a fact in itself warning against indiscriminate medication by the untrained. It is a striking fact that the sensitivity to the drug noted in fever may continue in the temporarily afebrile and convalescent persons, with resulting subnormal temperatures. "It is not allowable, therefore," Barbour writes, "to state that antipyretics reduce an elevated but not a normal temperature; a more correct formulation of the facts is that antipyretics reduce the body temperature in fever cases (including temporarily afebrile and convalescent phases) but not in normal persons."

Why a drug should provoke increased heat elimination in fever, but not in health, is not easy to understand. That the phenomenon is not due to a lack of combustible material in the sick, for instance, to a decrease in the glycogen store of the body, has been determined; for Barbour³ has already demonstrated that feeding a carbohydrate, such as glucose, may actually enhance the fall in temperature when acetylsalicylic acid is given, rather than counteract it by increased metabolism. The precise nature of the peculiar sensitivity to such antipyretics therefore remains to be further elucidated.

THE INFLUENCE OF NUTRITIONAL CON- DITIONS ON TUMOR GROWTH

One of the striking differences between cancer and infectious processes is exhibited in their opposite modification by conditions of nutrition, either local or general. Ligation of the lingual artery is a classical procedure for reducing the rate of growth of an inoperable carcinoma of the tongue, but no one would recommend such a procedure in the treatment of any sort of infectious process in this location. Old age, deficient nutrition, loss of blood, chronic diseases, and intercurrent infections are all recognized as commonly reducing the rate of growth of tumors, and it is axiomatic that carcinoma in the young and well nourished is commonly characterized by rapid development to a fatal termination. Equally certain it is that the

2. Barbour, H. G., and Devenis, M. M.: Antipyretics, II, Acetylsalicylic Acid and Heat Regulation in Normal Individuals, Arch. Int. Med. **24**: 617 (Dec.) 1919. Barbour, H. G.: Antipyretics, III, Acetylsalicylic Acid and Heat Regulation in Fever Cases, *ibid.*, p. 624.

3. Barbour, H. G.: Proc. Soc. Exper. Biol. & Med. **16**: 136, 1919.

effects of these conditions on most if not all known infections is exactly the opposite of what it is in cancer. While with human cancer occasional exceptions to the foregoing general rules are observed, it is probable that, could all conditions be controlled or evaluated accurately, the exceptions would be rare indeed. Cancer in experimental animals can be controlled and studied under more satisfactory conditions, and such observations as have been thus made support the generalizations that are commonly accepted concerning the influence of nutrition on growth.

Experiments in which the diet of animals has been restricted have commonly shown that deficient food intake reduces the rate of tumor growth. A dietary deficient in an essential amino-acid may reduce the growth rate of inoculated tumors, just as it decreases the rate of growth in young animals.¹ Diets deficient in vitamins reduce the rate of growth of tumors,² while vitamin-rich diets have been said to favor tumor growth.³ As most of these experiments have been performed with inoculated tumors, which undoubtedly behave differently from spontaneous tumors, particular significance attaches to the observations of Maud Slye⁴ on the influence of pregnancy and lactation on the behavior of spontaneous tumors in the mammary gland of mice. Thirty each of nonreproducing and of reproducing females with spontaneous tumors of the same type, alveolar tubular carcinoma of the mammary gland, were carefully studied and compared. Without exception the amount of tumor grown by a female while reproductive was strikingly less than during her nonreproductive period, despite the fact that the tumors were in tissues that are stimulated to great activity during reproduction. These exact observations corroborated what had been observed as a general principle in handling great numbers of other mice not accurately measured and watched as in this special study. As between reproducing and nonreproducing females, the difference in growth was remarkable. While the nonreproducing females lived rarely more than six weeks after the tumor was first observed, the average duration of life having been thirty-six days, the reproducing females frequently lived nearly a year, the average being 178 days, and many bore from six to eight litters. Especially remarkable are the figures for the rate of growth of the tumor as determined by frequent measurements, for in the nonreproducing mice the average daily growth was 999.4 c.mm., whereas in the reproducing females during the period of active reproduction, growth almost ceases, averaging in this series only 7.75 c.mm. After a reproducing mouse ceases reproduction, the rate of growth augments rapidly, so that the tumor may increase in size more in a few days than in as many months during reproduc-

tion. In the same mice that averaged only 7.75 c.mm. daily growth during reproduction, the rate after reproduction had ceased was 686 c.mm.

From these and other observations it would seem that while a tumor can withdraw for its own growth nourishment needed for its host, and evidently takes precedence over the somatic tissues in its affinity for nutritive supplies, the fetus in its turn takes precedence over the tumor, even as it does over the somatic tissues of its mother which it draws on for its nourishment, whatever the cost to the maternal organism. As Miss Slye says, the prolonged hiatus between pregnancies greatly complicates the study of the relation between pregnancy and tumor growth in the human species. During this prolonged hiatus the tumor may draw off the energy which would have continued to be used in reproduction if the pregnancies were not widely separated, just as is the case in mice kept constantly impregnated. This would account for any apparently conflicting testimony in human experience as compared with these studies. Finally, it is to be noted that in mice, as in women, infections in the pregnant are usually exceptionally virulent and usually quickly fatal, wherein we have another example of opposite biologic behavior of tumors and infections.

RECENT OBSERVATIONS ON THE CEREBROSPINAL FLUID

The cerebrospinal fluid has come to occupy an important place in modern clinical procedure. It is now frequently removed for diagnostic examination or therapeutic purposes; furthermore, the subarachnoid spaces which it occupies are sometimes utilized for the introduction of drugs intended to act on the nervous system. The determination of the mode of origin of the cerebrospinal fluid and its precise functions and physiologic relations to the various contiguous structures is obviously important. Unfortunately, the difficulties of experimentation in connection with this, as with many other parts of the central nervous system, have retarded progress. It need not be surprising, therefore, if some of the current views must be subjected to revision in the light of newer information or a more critical examination of beliefs already adopted.

One of the conclusions reached in recent years by a number of investigators, and already widely quoted, asserts that the cerebrospinal fluid is actively secreted by the choroid plexuses. Some writers believe that it is generated only within the ventricles, particularly the lateral ones, by a truly secretory process. It is pointed out that when the pathways by which the ventricles communicate with other parts of the brain are obstructed, the fluid collects so as to produce an internal hydrocephalus. Becht,¹ to whom we owe an unusually elaborate investigation of the subject coupled with a

2. Benedict, S. R., and Rahe, A. H.: *J. Cancer Res.* **2**: 159 (April) 1917.

3. Corson-White, E. P.: *Pennsylvania M. J.* **22**: 348 (March) 1919.

4. Slye, Maud: *J. Cancer Res.* **5**: 25 (Jan.) 1920.

1. Becht, F. C.: *Studies on the Cerebrospinal Fluid*, *Am. J. Physiol.* **51**: 1 (Feb.) 1920.

trenchant critique of existing views and evidence, has pointed out that the well-known facts of internal hydrocephalus do not prove the specific point of formation; for in the region under discussion, increased production of cerebrospinal fluid might result from activity of the choroid plexus, from stimulation of the ependyma cells lining the ventricles, from increased transudation from the capillaries, or from the formation of intracranial lymph: any one or all of these factors may be involved. Further, the rate of formation may be perfectly normal, the departure from the normal consisting merely in decreased absorption.

Another sort of evidence in support of the specific secretory origin of the cerebrospinal fluid has been sought in the observations that drugs and tissue extracts known to promote the activity of well recognized secretory structures, like the pancreatic glands, seem likewise to facilitate the output of cerebrospinal fluid. Why should not it, too, be placed in the category of the typical secretions? In answer to this, Becht has pointed out the close dependence of the pressure and flow of the fluid on the arterial and venous pressures that exist at any corresponding period in the skull; and according to him, all the changes in the fluid pressure and fluid outflow that have been offered as proof of the secretory mechanism of formation of the cerebrospinal fluid can be traced to alterations in these circulatory factors. If this is true, then the proof that the fluid is undoubtedly formed by secretion must be abandoned until more cogent evidence is produced for the participation of active cellular processes. While admitting that the choroid plexuses may represent one source of the cerebrospinal fluid, Dercum² ventures to believe that it has a further source in the general serous surfaces of its containing cavities.

Another upset of current traditions concerns the possibility of absorption from the subarachnoid spaces. If substances can be rapidly transferred to the nervous system by absorption from the cerebrospinal fluid, the possible importance of intradural injections in medication of the brain and cord is at once suggested. Meltzer³ has come to the conclusion that such injections do not produce the typical effects of an intravenous injection; and Becht has been unable to demonstrate the absorption of potent drugs from the dural canal when they have been introduced with suitable care to avoid undue pressure or direct traumatic entrance into blood vessels. Coincidentally, Dercum has asserted that "attempts at medication of the brain and cord through the subarachnoid space, as in the Swift-Ellis method, are unscientific, as substances introduced into the cerebrospinal fluid rapidly disappear by passing out through the arachnoidal villi and the lymph spaces without in the slightest degree penetrating the nervous parenchyma; the beneficial effects hitherto ascribed to the Swift-Ellis and kindred methods are due entirely

to the incidental spinal drainage." He adds that medication of the nervous parenchyma must be attempted through the alimentary tract, through the skin, through the areolar tissue, or directly through the blood.

If we are to abandon some of the current beliefs regarding the production and escape of the cerebrospinal fluid, what shall be said about its rôle? Dercum regards it as "preeminently a fluid for the hydraulic suspension of the brain and cord; its function is essentially hydrostatic." Having a chemical composition essentially like that of an isotonic saline solution, it has no action on the tissues with which it comes into contact, and, if we may follow Dercum, it has no special function in the nutrition of the brain and cord, which takes place as does that of other tissues.

Current Comment

PHYSICAL AGENTS AS PROVOCATIVES OF IMMUNITY REACTIONS

The well marked resistance of certain species to infection with germs usually harmful or fatal to others is commonly designated as natural immunity, because it seems to be "a natural biologic attribute of the species, as much a characteristic property as are its anatomic or physiologic properties." Immunity can also be acquired, notably after an attack of certain diseases. This "acquired immunity" is assumed to be a manifestation of some biologic stimulus or factor which at once differentiates it in some unexplained way from the usual responses of the organism to chemical and physical agencies. The hope of successfully inducing those reactions which are the basis of immunity of any type whatever rests on the possibility of analyzing the factors concerned and of imitating their functions. Several years ago, Murphy showed that there is likely to be an actual increase in the circulating lymphocytes, accompanied by hyperplasia of the lymphoid elements following cancer inoculation into immune animals. If this crisis was prevented by the destruction of the lymphocytes, the immunity of the animal was destroyed. By repeated small doses of roentgen rays, an animal could be practically depleted of lymphoid tissue without apparent injury to other important structures, and without detectable influence on the animal's general health. In such an individual, immunity was replaced by susceptibility to cancer inoculation. The beneficial response of the lymphoid tissue can be induced in animals by means of injection of living tissue. Murphy¹ has lately ascertained, however, that purely physical methods of heightening the activity of the lymphoid centers in the spleen and lymph nodes also are available. If single small exposures to roentgen rays of suitable quality are employed, a good response is secured. Furthermore, dry heat ranging from 55 to 65 C. applied to the whole animal for five minutes was found to produce a stimulation of the lymphocytes and of lymphoid tissue

of marked intensity, the increase in the number of lymphocytes persisting for a number of days. Murphy states, as the results of recent experiments at the Rockefeller Institute for Medical Research, that the lymphocytosis and lymphoid hyperplasia induced by these two physical agents are associated with an immunity to transplanted cancer equally as great as that arising from tissue injections. There is something more readily measurable and better definable in heat or in roentgen rays than in such vague somethings as are tissue extracts at present. To secure a wholesome reaction of possible far reaching importance in the body by means of such physical agents is a step in the direction of progress, however far it may still be from even speculation as to any application to human conditions. Murphy cannot state at present whether the tissue injection, the small dose of roentgen rays, or the dry heat induce changes in the organism other than those associated with increase in the lymphoid tissue which would account for the immunity; but the evidence now at hand points at least to the lymphoid tissue as an important agent in the immunity reaction to transplanted cancer of mice.

BONDS NOT NECESSARY FOR PHYSICIANS

Apparently some of the by-products of prohibition are going to be as interesting as the main issue. Without intending to cast any slurs on our great and noble sister profession, it is indeed an ill wind that some lawyer cannot manipulate to his advantage. Judging from the letters received, physicians are being circularized by a member of the legal fraternity who has devised a method of helping them to comply with the prohibition law with the greatest amount of ease and convenience to themselves and with profit to him. The circulars have this interesting legend printed in large red type on the face of the envelop: "What the U. S. Government Allows You to Do. I Know the Law. I Will Do Everything but Sign Your Name." The circular offers to assist physicians in securing government permits to purchase or prescribe liquor. While it does not expressly say so, the impression conveyed to the uninformed physician is that every practicing physician must file a bond in order to purchase or prescribe any amount of liquor. This is not the case. As stated in the abstract¹ of Internal Revenue Regulation No. 60, physicians desiring to purchase and prescribe liquors in their practice are required to procure a permit to prescribe. This can be obtained by filling out an application on Form 1404 in triplicate and filing it with the federal prohibition director of the state in which the physician is licensed to practice. This permit, when issued, allows him to prescribe liquor for medicinal purposes only, and when such liquor is necessary to afford relief from some known ailment. It also allows him to purchase not more than six quarts of liquor during any calendar year for professional use only. Bonds need not be filed by physicians, dentists or veterinarians, or by hospitals or sanatoriums unless required by the com-

missioner. It is not necessary for physicians to pay five dollars or any other amount to any lawyer or bonding company. No fee is required for registering and securing a permit under the prohibition law, and the government officers can and will do all that is necessary to assist a physician to procure a permit without any cost to him. THE JOURNAL has endeavored to keep its readers informed regarding the provisions of the prohibition law. It will continue to do so in the future. The requirements for registration under the law are not difficult; however, if any of our readers are in doubt as to what to do in order to comply with the law, we shall be glad to advise them.

AN ADVANCE IN ROENTGENOGRAPHIC TECHNIC

Even in this day of receptive minds eager for new truths, it may be years before discoveries of great importance to science are brought into general use. In 1912, Lorey¹ happened to roentgenograph the abdomen of a patient who several days before had had air injected into his peritoneal cavity to replace ascitic fluid removed. It was discovered that some of the nitrogen was still present, and this had allowed the intestine to drop out of the way, so that beautiful pictures were secured showing the outlines of the liver, spleen, kidneys and other organs. During the next year, Weber² did considerable work to show the possibilities of this method. It was not until 1918, however, that much interest was taken in the subject. Since then a number of papers have appeared in the German, French and Italian journals. Probably the first plates of this type to be shown in America were presented last year at the annual session of the American Medical Association, by Stein and Stewart of New York. Many who saw these roentgenograms felt that they were looking on a great advance in roentgenologic technic, perhaps the most important as regards intra-abdominal diagnosis since Cannon introduced the bismuth meal. It is remarkable that injection of gas into the peritoneal cavity through a needle reveals so clearly the liver, the kidneys, the spleen, the walls of the stomach and intestine, the uterus and its adnexa, the diaphragm and the lower ribs. Undoubtedly the method may be used to show also the point of origin of obscure abdominal tumors. Most of the work has been done with oxygen, but this takes a day or more to be absorbed, during which time the patient is often compelled to remain in bed. It has now been shown that carbon dioxid can be used instead.³ As this is absorbed in half an hour, the procedure may be carried out in the office, and the patient can return to his home or to his work. So far no accidents have been reported, and there seems to be little reason for fearing any so long as the cases are properly chosen. Naturally, it would be unwise to inject a liter or two of gas into the abdomen of a man with a subphrenic abscess or with adhesions around an area of localized peritonitis. As the distention of the

abdomen always causes considerable discomfort and sometimes acute pain, particularly in the shoulders, the procedure will probably always be limited to the study of special cases. In this issue of *THE JOURNAL*, Whitman⁴ describes from a personal experience the point of view of the patient submitted to this method.

Association News

THE NEW ORLEANS SESSION

Special Social Events for Women Physicians

A luncheon for visiting women physicians will be tendered by the women physicians of the Southern Medical Association on Tuesday, April 27, at the St. Charles Hotel, and the annual banquet for women physicians will take place at the Louisiana, Wednesday, April 28, at 6 p. m. Reservations should be made through Dr. Margaret Bowden, 1217 Calhoun Street, New Orleans. The cost per cover is \$4.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Urologic Section Formed.—A urologic section of the Los Angeles County Medical Society has recently been organized with sixteen charter members and the following officers: president, Dr. Granville MacGowan; president-elect, Dr. Ralph R. Campbell; vice president, Dr. Robert V. Day, and secretary, Dr. Herbert A. Rosenkranz.

Personal.—Dr. Irving R. Bancroft, Los Angeles, has been appointed secretary and executive officer of the state board of health succeeding Dr. Wilfred H. Kellogg, Sacramento. —Dr. Daniel Crosby has resigned as city health officer of Oakland. —Dr. Walter Lindley, Los Angeles, has been appointed a member of the state board of health succeeding Dr. Lemoyne Mills, term expired. —Dr. William B. Kern, superintendent of the Norwalk State Hospital, has resigned to resume private practice after sixteen years of institutional work.

COLORADO

New Officers.—Lake County Medical Society at Leadville, January 15: president, Dr. Franklin J. McDonald; vice president, Dr. Allan J. McDonald, and secretary-treasurer, Dr. Elwood B. Lynch, all of Leadville.

CONNECTICUT

Resigns After Long Service.—Dr. Max Mailhouse, professor of neurology in Yale University, has resigned after twenty years' service with the institution.

Health Center Organized in New Haven.—A health center has been organized in New Haven under the combined leadership and financial support of the municipal department of health, visiting nurse association, the New Haven chapter of the American Red Cross, and the New Haven Medical Society. The health center will aim to build up the health as well as to detect the physical defects of the 20,000 inhabitants in the selected district, which is largely of Italian stock, and it is expected that the center will be in full operation by July 1. Its temporary quarters are 184 York Street.

ILLINOIS

Dr. Bartlett Speaks Before County Society.—Dr. Willard Bartlett, St. Louis, gave an address on "Goiter Surgery," before the Madison County Medical Society at its meeting in Edwardsville, April 2.

Free Exercise of Healing Art Asked.—A petition from the "central health committee," asking that the new constitution of the state permit the free exercise of the healing art was presented at the constitutional convention by Delegate Cruden, and referred to the bill of rights committee.

Personal.—The offices of Drs. A. B. Scott, Paul B. Kionka and L. A. Lighthart, Melrose Park, were destroyed in the tornado which struck that village, March 28. —Dr. Elmer S. Allen, Arcola, who was operated on several weeks ago at the Union Hospital, Terre Haute, for the removal of gallstones, has recovered and returned home.

Addition to State Hospital.—The state of Illinois has begun work on the addition to the Alton State Hospital, to cost, \$500,000. The plans call for six cottages capable of housing 100 patients, in addition to a dining room and kitchen, and construction of two buildings to house tuberculosis patients, and the erection of a hospital building.

Plead Guilty to Failure to Report.—Drs. Henry S. Bennett, Joseph D. McKelvey, Chester C. Sloan and Prudens R. Sterck, Moline, and Arthur E. Williams, Rock Island, are said to have pleaded guilty, March 25, to charges of violating the city health law by failing to report births within the required five day limit, and to have been fined \$10 and costs in the Moline police court. The fines were suspended, but the physicians were held for the costs in the case.

Chicago

Institute to Hear Address on the Atom.—There will be a meeting of the Institute of Medicine of Chicago, April 16, at 8 p. m., in the City Club, at which Prof. R. A. Milliken, University of Chicago, will speak on "The Twentieth Century Contributions to Our Knowledge of the Atom." All interested are invited.

Karalius Declared Insane.—Dr. Anthony J. Karalius, who charged that a federal prohibition agent obtained a prescription for liquor by giving a Masonic distress signal and later said he had paid agents \$1,000 not to prosecute him, was found of unsound mind, March 31, and will be committed to an institution. Dr. Karalius was released on bond of \$2,000, April 2, but has been forbidden to practice medicine or issue prescriptions for narcotics or liquors, pending trial.

INDIANA

Tuberculosis Exhibit Tour.—The state board of health tuberculosis exhibit automobile has started on a tour of the rural districts of the state.

University Centennial.—Indiana University will hold its centennial celebration May 5, 6 and 7. May 5 will be given over to the exercises of the medical department at Indianapolis, and all physicians are invited to be present at the meetings on that day.

University to Operate Dispensary.—The board of health of Indianapolis, at the meeting, March 15, approved a contract with the Indiana University School of Medicine for the operation of a city dispensary for 1920. The university agreed to operate the dispensary and provide supplies for \$825 a month.

Personal.—Dr. Frank C. Wade, Howe, sustained a fracture of the arm when his sleigh overturned recently. —Dr. J. C. Fulton, Bluffton, rounded out a half century of practice in Wells County, March 11. —Dr. Frederick J. Schulz, Fort Wayne, for thirteen years physician to the General Electric Company, Fort Wayne, has resigned. —Dr. Harry M. Pell, Brazil, has been appointed local physician for the Pennsylvania system, succeeding Dr. Lewis L. Williams, deceased. —Dr. Aldine E. Morgan, Lafayette, has returned to the Indiana State Soldiers' Home as chief surgeon.

IOWA

Venereal Disease Clinic.—It is announced that a clinic for the free treatment of venereal diseases will be established in Cedar Rapids, as the result of a survey made by Dr. Oliver C. Wenger, U. S. Public Health Service.

Personal.—Dr. Charles Magoun, Sioux City, has been appointed physician of Woodbury County, succeeding Dr. Guy E. Barr, Sioux City. —Dr. M. Charles Mackin, Knoxville, superintendent of the Iowa State Inebriate Hospital, Knoxville, has been appointed assistant alienist to the State Hospital for the Insane, Skillman, N. J. —Dr. Leon C. Havens, acting head of the department of epidemiology in the State University of Iowa, Iowa City, has been called to a chair in Johns Hopkins University, Baltimore.

4. Whitman, Armitage: Oxygen Inflation of the Peritoneal Cavity: A Personal Experience, *THE JOURNAL*, this issue, p. 1021.

MARYLAND

Emerson in Baltimore.—Dr. Charles P. Emerson, professor of medicine and dean of the University of Indiana School of Medicine, Indianapolis, delivered an address on "Environmental Medicine," at the Johns Hopkins School of Hygiene and Public Health, March 29.

Workrooms for Wounded.—Two portable buildings will be erected this week on the grounds of the United States Marine Hospital to give the patients a place in which to do handiwork. Four members of the reconstruction division of the U. S. Public Health Service, under the direction of Miss Elizabeth Winn, chief reconstruction aide, are in charge of the division of occupational therapy, to which one of the buildings will be devoted. The other will be given over to a physiotherapy department.

Personal.—Dr. William S. Halsted has received a diploma of honorary foreign membership in the Royal College of Medicine of Belgium. Dr. John M. T. Finney has been awarded honorary fellowship in the Royal College of Surgeons of England.—Dr. Warren H. Lewis of Johns Hopkins Medical School has been elected an honorary member of the Society of Medicine of Ghent, Belgium.—Dr. Ross McC. Chapman, the new superintendent of the Sheppard and Enoch Pratt Hospital, Towson, assumed his duties, April 1.

MASSACHUSETTS

Personal.—Dr. George R. Fessenden, Ashfield, has been appointed associate medical examiner (coroner), for Franklin County.—Dr. Richard J. R. Caines, Boston, has returned after eighteen months overseas.

Dean Lewis in Boston.—Dr. Dean D. Lewis, professor of surgery (elect) in Chicago University, has been acting for two weeks as surgeon-in-chief pro tempore, in charge of Dr. Harvey Cushing's service at the Peter Bent Brigham Hospital, Boston.

Staff Meeting.—A clinical meeting of the outpatient department medical staff of the Massachusetts General Hospital was held, April 7. Dr. Lloyd T. Brown, Boston, presented a paper on "Bodily Mechanics in Relation to Medicine," and Francis M. Rackemann, Boston, one on "Bronchial Asthma."

Resigned, Not Deceased.—The report that recently appeared in a Boston paper announcing the nomination of Dr. G. Forrest Martin as a trustee of the state infirmary in place of Dr. Leonard Huntress, deceased, should have read "in place of Dr. Leonard Huntress, resigned." Dr. Huntress is alive and well.

Complimentary Luncheon to General Wood.—The Class of 1883 of Harvard Medical School, of which Major-General Leonard Wood is a member, will give a complimentary luncheon to him at Symphony Hall, Boston, April 13, from 12 to 2:30. The speakers will be Dr. Henry Jackson, Boston, president of the class, Dr. Alfred Worcester, Waltham, president of the Massachusetts Medical Society, and General Wood.

MICHIGAN

Influenza Deaths.—During the seven weeks of the influenza epidemic in Detroit, during January and February, the mortality rate was 2 per thousand. During a similar period at the beginning of the epidemic in 1918, the mortality was slightly less, but resulted finally in the deaths of 0.28 per cent. of the population.

Personal.—Dr. Theodore S. Crosby has been appointed health officer of Wakefield.—Dr. Bruno L. Schuster, Jackson, health officer of Jackson County, has resigned.—Dr. Mabel E. Elliott, Benton Harbor, who was captured with a party of Armenian relief workers during a recent raid of the Turks, is reported to have escaped.

MISSISSIPPI

Smallpox.—Smallpox of virulent type is said to be prevalent in half of the counties of the state. The state sanitary inspector, Dr. Cyrus M. Shipp, Water Valley, announced, March 27, that twenty deaths had occurred from this cause in Jones County. During the last fourteen days of March, 785 cases were reported from forty-one counties.

Six-County Medical Society Installation.—At the meeting of the North Mississippi Six-County Medical Society, composed of Tippah, Benton, Union, Marshall, Yalobusha and Lafayette counties, March 17, Dr. Ira B. Seale, Holly Springs, was installed president; Dr. George W. Sisler, Waltham, vice president, and Dr. Billy S. Guyton, Oxford, secretary.

Health Campaign Planned.—To carry out the cooperative idea between the work of the state board of health and the American Red Cross, plans are being made for the initiation of a health campaign in Lafayette County. The state board of health will appropriate \$5,000 toward this cause, and the secretary of the Lafayette County chapter of the American Red Cross \$2,500, provided the citizens of the county, through its board of supervisors, will provide the \$2,500 needed.—At a meeting held in McComb, March 22, plans for the special health campaign to begin in McComb were outlined. Dr. W. D. Beachman, Summit, health officer of Pike County, has moved his office to McComb and has associated with him in the work Red Cross nurses and assistants. McComb has added \$1,000 to the Rockefeller fund in order that special work may be done.

MISSOURI

Mayoral Candidates Outline Policies.—March 20, at Mercy Hospital, Mayor Cowgill and Walter H. Foster, candidates for mayor of Kansas City, outlined their proposed policies with regard to hospital and health boards to the members of Jackson County Medical Society.

Personal.—Dr. Robert Vinyard, St. Louis, has been appointed assistant physician to the Frisco Hospital, Springfield.—Dr. George W. Cale, Jr., after twenty-two years' service as chief surgeon of the St. Louis and San Francisco system, announces his retirement, April 1, to resume private practice.—Dr. Wenzel C. Gayler has resigned as second vice president of the St. Louis Medical Society.—Dr. Harold B. Scovern, Carrollton, has been appointed deputy state health commissioner.

NEBRASKA

Personal.—Dr. Hiram W. Orr, Lincoln, has been made editor of the *Journal of Orthopedics*.—Dr. Earl W. Fetter, North Platte, has been made physician of North Platte, succeeding Dr. John S. Simms, North Platte, resigned.—Dr. and Mrs. Charles R. Gannaway, Stuart, have disposed of their hospital to engage in the Near East relief work.

Hospital Items.—The campaign put on by the Lincoln Commercial Club, early in March, to secure \$100,000, which, added to a similar amount voted by Lincoln last spring for a city hospital, will make up the amount necessary to build a hospital, has been successful and the hospital will be built this summer.—Long Pine Community Hospital was formally opened, February 17, and is in charge of Dr. Albert G. Rasck, Long Pine, formerly of Chicago.—The citizens of Sydney and tributary territory have organized a hospital association which will build a hospital this summer.

NEW YORK

Cash Prize Awarded.—The Merritt H. Cash Prize of the New York State Medical Society has been awarded to Dr. Herman B. Sheffield for his essay on infantile paralysis.

Society Condemns City Laboratory Plan.—The Albany County Medical Society, at its meeting, March 10, condemned the plan of expending \$20,000 for alterations of the old pumping station on Manning Boulevard for the purpose of establishing a municipal bacteriologic laboratory, and adopted a resolution urging the mayor to register the opposition of the medical fraternity to the scheme.

New Officers for Women's Society.—The forty-sixth annual meeting of the Women's Medical Society of New York State was held March 22, in New York City, under the presidency of Dr. Elizabeth B. Thelberg, Poughkeepsie, and the following officers were elected: president, Dr. Lois L. E. Gannett, Adams; vice presidents, Dr. Florence I. Staunton, Utica, Mathilda K. Wallin, New York City, and M. Louis Hurrell, Rochester; secretary, Dr. Harriet M. Doane, Fulton, and treasurer, Dr. Elizabeth L. Shrimpton, Syracuse.

State Aid in Local Health Work.—A bill introduced in both houses of the state legislature proposes the establishment of health centers, to be supported by the state funds in addition to local appropriations. Grants are to be made for the construction and operation of hospitals, dispensaries and clinics in rural and urban communities. Facilities for bacteriologic and pathologic diagnosis and for consultation are to be provided. The health centers also will serve as headquarters for the district health service, for public health nursing, medical school inspection and public health education. The board of managers of the state charities aid association has adopted resolutions favoring passage of the measure.

New York City

Hospital for Incurables Opened.—The Beth Abraham Hospital for Incurables, with accommodation for seventy-five patients, was opened March 22. A campaign for \$200,000 has been launched for the erection of new buildings.

Course in Fractures.—A course in fractures was begun at the Cornell Medical College, April 5, and will continue until April 30, on Mondays, Wednesdays and Fridays. The course consists of two consecutive hours of lectures and demonstrations, beginning at 2 o'clock. Dr. Joseph A. Blake will give seven exercises; Dr. George W. Hawley, six, and Dr. James M. Hitzrot, five. In addition to the first three, Dr. Alexis Carrel will also give one lecture. Other exercises will be held by Dr. Henry H. M. Lyle, Dr. Burton J. Lee and Dr. John C. A. Gerster. The profession is cordially invited.

Distribution of United Hospital Fund.—Officials of the United Hospital Fund announced that they have distributed \$400,000 among the forty-six member institutions. This represents double the amount each hospital received last year from the organization. Among the larger amounts distributed were: St. Luke's Hospital, \$27,850.90; Mount Sinai Hospital, \$27,752.32; New York Hospital, \$43,118.26; Presbyterian Hospital, \$18,472.12; Lincoln Hospital, \$16,567.90; Lenox Hill Hospital, \$14,409.42; Roosevelt Hospital, \$13,318.92; Post-Graduate Hospital, \$11,868.72; Orthopedic Hospital, \$21,518.42; Hospital for Ruptured and Crippled, \$15,307.34, and Montefiore Home, \$35,271.28.

OHIO

Resignations.—Dr. William Wylie Scott, city physician of Canton for three years, has resigned.—Dr. Charles G. Augustus, health director of Springfield for three years, has resigned.—Dr. Ernest Zueblin has resigned from the staff of the Cincinnati Tuberculosis Sanatorium and has been succeeded by Dr. Reuben Erickson.

Illegal Practitioners Prosecuted.—A report states that Dr. E. C. Branch was fined \$50 and costs, March 24, for advertising himself in Ohio as a practitioner of medicine without having first obtained a license. Charges also were filed against D. A. Donovan, an optometrist, for advertising himself as a practitioner of medicine and surgery in Wooster, without having first secured a license. Although an optometrist, Donovan is said to have used the unqualified title of "Dr." in his advertisements. Charges have been filed, also, against a woman named Mary Lottig in Cleveland for illegal practice of medicine.

PENNSYLVANIA

Weir Mitchell Entertainment Fund.—The Weir Mitchell Entertainment Fund will give a dinner to the Fellows of the College of Physicians of Philadelphia, at the College, April 15, at 7 o'clock.

Personal.—Dr. Patrick H. Weeks, Warren, has been appointed physician to the Northern Indiana Penitentiary, Michigan City.—Dr. Karl Schaffe, Philadelphia, for eight years head of the tuberculosis dispensary work in the state department of health, and Dr. Dorothy Child, Philadelphia, director of the child health bureau of the department, have resigned.

Health Insurance Commission.—The governor has appointed a commission to investigate accidents and sickness not compensated under the workmen's compensation act of Pennsylvania. The members named by the governor are: William Flinn, Pittsburgh; William Draper Lewis, Dr. Francis D. Patterson, secretary, Dr. Gassaway Oram Ring and William H. Kingsley, Philadelphia; members named by the president pro tem of the senate: Senators S. J. Miller, Clearfield County; Morris Einstein, Allegheny County, and Charles W. Sones, Lycoming County, and members named by the speaker of the house, William T. Ramsey, Delaware County, chairman; John M. Flynn, Elk County, and Theodore Campbell, Philadelphia.

RHODE ISLAND

Associate Editors Appointed.—Drs. William F. Barry, Woonsocket; Charles S. Christie, River Point; Asa S. Briggs, Ashaway, and Norman M. Macleod, Newport, have been appointed associate editors of the *Rhode Island Medical Journal*.

Passes Ninetieth Birthday.—Dr. Horatio R. Storer, Newport, celebrated his ninetieth birthday anniversary, February 27. Dr. Storer was recently given the degree of LL.D. by

Fordham University, New York City, in recognition of his activities in matters of disease prevention.

Tuberculosis Survey.—The state association for the prevention of tuberculosis has engaged Prof. C.-E. A. Winslow of the Yale School of Medicine to make a survey of tuberculosis conditions in the state and of the work which is being done by different organizations for its control.

Fight Against Mosquitoes.—The bill appropriating \$20,000 to assist cities and towns in the extermination of mosquitoes has been passed. Under the provisions of this act, communities making appropriation for the mosquito extermination will receive from the state an amount equal to the sum, which they may expend in actual work, not to exceed \$3,000.

League for the Suppression of Tuberculosis.—The Providence League for the Suppression of Tuberculosis was organized in 1906 as a committee of the society for organizing charities. A charter has recently been obtained and the league has been formed into an entirely new and separate organization with the above name. Dr. Jay Perkins is president and Dr. Jeannie O. Arnold, secretary. The league has been chiefly occupied with relief and educational work, and with maintaining a preventorium. It hopes to expand greatly its field of operation, and Dr. Elliott Washburn, Providence, has been selected as its general agent.

New Officers.—Newport County Medical Society at Newport, January 22, elected these officers: president, Dr. Abiram F. Squire; vice presidents, Drs. Charles W. Stewart and Norman M. Macleod; secretary, Dr. Alexander C. Sanford, and treasurer, Dr. Douglas Jacoby, all of Newport.—Providence Medical Association, January 5, elected: president, Dr. Dennett L. Richardson; vice president, Dr. Frank T. Fulton; secretary, Dr. Raymond G. Bugbee, and treasurer, Dr. Charles F. Deacon.—Washington County Medical Society at Westerly, January 8, elected: president, Dr. Patrick J. Manning, Wickford; vice presidents, Drs. Henry L. Johnson, Westerly, and William T. Veal, Stonington, and secretary-treasurer, Dr. William A. Hillard, Westerly.

TENNESSEE

Personal.—Dr. Sydney Thompson, Nashville, has so far recovered in health that he has returned to his work as assistant superintendent at the Central Hospital.

New Officers.—Jackson County Medical Society, at Kingsboro, March 1: president, Dr. John D. Quarles, Whitlyville, and secretary, Dr. Roscoe C. Gaw, Gainesboro.—Giles County Medical Society: president, Dr. George D. Butler, Pulaski; vice president, Dr. William H. Cole, Minor Hill; secretary, Dr. Charles A. Abernathy, Pulaski, and treasurer, Dr. George C. Grimes, Pulaski.—Lincoln County Medical Society: president, Dr. James M. Shelton, Kelso, and secretary, Dr. Jacob M. McWilliams, Fayetteville.—Washington County Medical Society: president, Dr. James G. Moss, and vice president, Dr. Lee K. Gibson, both of Johnson City.—Rutherford County Medical Society: president, Dr. Matthias B. Murfree, Murfreesboro; vice president, Dr. John M. Shipp, Readyville, and secretary-treasurer, Dr. James A. Scott, Murfreesboro.

TEXAS

Personal.—Dr. W. H. Minton, Houston, has been appointed assistant state health officer, succeeding Dr. Douglas Largen, resigned.

Physicians Want Quiet Zones.—The physicians of San Antonio have requested the city council to establish zones of quiet around the hospitals in that city.

Malaria Fight.—The department of public health of Dallas has spent about \$6,000 in malarial control work, including cleansing of streams, confining them to narrow channels, and the stocking of streams with minnows to feed on the malaria-bearing larvae.

WEST VIRGINIA

New Officers.—Mercer County Medical Society at Bluefield, January 22: president, Dr. Charles T. St. Clair, Bluefield; vice presidents, Drs. Bernard S. Clements, Matoaka, Francis T. Ridley, Bluefield, and Walter W. Harloe, Matoaka; secretary, Dr. Edward H. Thompson, Bluefield, and treasurer, Dr. Thomas E. Peery, Bluefield.—Raleigh County Medical Society at Beckley, January 9: president, Dr. Kyle M. Jarrell, Beckley; vice presidents, Drs. Ira M. Fisher, Stotesbury, McRae C. Banks, Raleigh, and William C. Mays, Beckley; secretary-treasurer, Dr. Fred Stansbury, Beckley.

CANADA

Personal.—Dr. Frederick Montizambert, Ottawa, director-general of public health for Canada, was knocked down by a street car in Ottawa, January 19, and his clavicle was fractured.

Dental Faculty Created.—The faculty of dentistry has been created in McGill University, Montreal. Heretofore dentistry was administered under the medical faculty. There are 400 students in attendance in this department.

Licensure in Charge of University.—A bill has been introduced into the parliament of Alberta placing under control of the University of Alberta the examination and registration of applicants who desire to practice the various branches of medicine in that province. The university already has in charge the registration and examination of nurses and it is expected that registration of those practicing law, pharmacy and dentistry will be similarly provided for. This appears to be a move in the right direction. If the university is given a free hand in the educational qualifications necessary, it will be the safest body to have these matters in charge. The entire problem of medical cults rests on educational qualifications. It is hardly probable that the university will establish more than one standard of qualifications for those who are to treat the sick.

Hospital News.—Dr. Clarence M. Hincks, Toronto, secretary of the Canadian Mental Hygiene Commission, was recently in Halifax, N. S., in connection with the establishment of a psychiatric clinic in that city. It is probable that the commission will shortly take a survey of the mentally afflicted in Nova Scotia.—Brandon, Man., is to have a new hospital at a cost of \$300,000.—The hospitals now receiving governmental aid in Alberta number forty-nine. It is expected that during the present year municipal hospitals will be established in ten new localities in Alberta.—At Keith, Alberta, a sanitarium is to be established for cases of tuberculosis. At first there will be 150 beds, but when the institution is finally completed its capacity will be for 300.—In Saskatchewan four union hospital districts have been established under the union hospital act. The areas selected are Battleford, Unity, Strasbourg, and Wynyard. Voting takes place on the scheme in March or April.—British Columbia will spend \$150,000 on hospitals and public institutions. Of this amount, \$85,000 will be for the feeble-minded, for whom a farm of 300 acres has been purchased on which cottages are being erected.—A new annex is to be added to the Provincial Royal Jubilee Hospital at Victoria, B. C. It is for the accommodation of venereal disease cases.

GENERAL

Conference of Social Work.—The National Conference of Social Work will open its forty-seventh annual session by a joint meeting with the National Child Labor Committee at New Orleans, April 14.

New Officers for Posture League.—At the annual business meeting of the American Posture League, March 13, the following officers were elected: president, Jessie H. Bancroft; vice president, Dr. Frederick R. Green, Chicago; secretary, Dr. Henry Ling Taylor, New York City, and treasurer, Dr. George J. Fisher, New York City. The annual public meeting of the league was held this week concurrently with that of the American Physical Education Association in New York City.

Bequests and Donations.—The following bequests and donations have recently been announced:

St. Peter's Hospital, Charlotte, N. C., a donation of \$20,000 from Mr. and Mrs. W. A. Irwine, Durham, N. C., as a memorial to their grandson, Hamilton C. Jones.

Polyclinic Hospital, Harrisburg, \$150,000, the result of a drive which closed, January 27.

Lewistown, Pa., Hospital, \$1,500 by the will of Harriet Thomas Kurtz. Blackford County, Ind., Hospital, a donation of three city blocks of land and \$5,000 for improvements, by Mrs. H. B. Smith, Hartford City.

Meeting of Industrial Physicians.—The American Association of Industrial Physicians and Surgeons will hold its fifth annual meeting at the Hotel Grunewald, New Orleans, April 26 and 27. Sessions will be held at 9 a. m. and 2 p. m. on each day, at which will be discussed the problem of the mentally and physically subnormal wage earner, the training of industrial physicians, the relationship of the industrial physician to the venereal disease problem, first aid and standardized surgical methods in industry, and the problem of compensation for sickness.

Carbon Monoxid in Vehicular Tunnels.—At its Pittsburgh station, the United States Bureau of Mines is making tests

to determine the amount and percentage of carbon monoxid in the exhaust gases of automobiles. The problem is assuming increasing importance in connection with plans for ventilating the long tunnels designed for vehicular traffic—a tunnel 5,700 feet long is under construction through the South Hills at Pittsburgh, one of 6,000 feet is proposed for Boston, and designs are being prepared for a tunnel 8,000 feet long to pass under the Hudson River between New York City and New Jersey. Coincidentally, experiments are being carried on by Dr. Yandell Henderson at the physiologic laboratory of Yale Medical School, to determine what percentage of carbon monoxid in the air may be safely tolerated for several hours.

FOREIGN

Oliver-Sharpey Prize.—Dr. Emile Roux of the Pasteur Institute, Paris, has been awarded the Oliver-Sharpey Prize for 1920 by the Royal College of Physicians of London.

Surgeon in Danish Cabinet.—Prof. Thorkild Røvsing, prominent Danish surgeon, chief of the surgical section of the Rigshospital, Copenhagen, and editor of *Hospitalstidende*, was minister of education in the cabinet of Denmark, formed March 30, and since reported dissolved.

Australian Commonwealth Public Health Service.—The government intends to proceed with the establishment of a federal health department. It is not likely that more will be attempted than the encouragement of research and the perfecting of statistical and other information between the existing state departments.

Scarcity of Ergot and Santonin in the Netherlands.—The *Nederlandsch Tijdschrift voor Geneeskunde* publishes a communication from two experts consulted dealing with the conditions in which ergot and santonin are indispensable and those in which they can be substituted by other drugs. The scarcity of these two drugs has impelled the authorities to urge physicians to be as saving in their use as possible.

King Umberto Prize.—The Rizzoli Orthopedic Institute, Bologna, Italy, announces that competition for the prize Umberto I has been opened. The prize of 3,500 lire (normally \$700) will be assigned by the provincial council of Bologna for "the best orthopedic work or invention." Both Italian and foreign physicians may take part in this competition. The regulations of the competition will be sent to any one who applies to Dr. G. Zanardi, president of the Rizzoli Institute, Bologna. The competition will close December 31.

The Boas Prize.—The second conference on diseases of the digestive glands and deranged metabolism is to be held at Hamburg in May with Prof. I. Boas presiding. The subjects appointed for discussion are duodenal ulcer; the consequences of dysentery from the standpoint of diagnosis and treatment; war experiences with diabetes; and the diagnostic importance of what we know in regard to the internal secretions as applied to diseases of digestive organs and metabolism. The Boas prize of 1,000 marks is to be awarded this year for the best article received in competition dealing with the influence of mastication on the secretion of gastric juice in health and in disease.

Red Cross League Items.—Senator Curaolo, president of the Italian Red Cross, has replaced Senator Frascara as a member of the board of governors of the league.—George C. Whipple, professor of sanitary engineering in the Medical School of Harvard University, has arrived in Geneva and taken up his duties as chief of the department of sanitation.

—Dr. Octave Monod has entered on his duties as assistant chief of the department of tuberculosis.—The league has undertaken, on behalf of the British Red Cross, to care for certain British patients in tuberculosis sanatoriums in Switzerland.—The League of Red Cross Societies has been elected an honorary member of the Statistical Society of Paris, and Mr. Knud Stouman, chief of the department of vital statistics, has been chosen representative of the general medical department of the league.—Dr. S. Burt Wolbach, Boston, of Harvard University Medical School and Dr. John L. Todd of McGill University visited Geneva on their way to Poland to discuss with Dr. Richard P. Strong, the chief medical director, the program which the league is to carry out in Poland in connection with the study of the etiology of typhus fever. Dr. Wolbach is chairman of the commission of the league; Dr. Todd, assistant chief, and other members of the commission are Drs. A. Bacot of the Lister Institute, London; Francis W. Palfrey, Boston; Monroe A. McIver, New York City; James W. Denton, Rhode Island, pathologist; Mr. Henry Pinkerton of the Massachusetts Institute of Technology, and Mr. Forrest A. Hardy, medical secretary.

Government Services

Health Conditions of the Army

For the week ending March 26 there is reported a slight increase in the number of new cases of measles, but the disease is not epidemic at any station. The increase was expected in connection with the arrival of new recruits as a result of a recruit drive, now nearing completion. The admission and noneffective rates are considerably lower than for the previous week, and are believed to be as low as can reasonably be expected for this season of the year. There were twenty-one deaths from disease reported during the week: eight were caused by tuberculosis and seven by pneumonia.

Public Health Service Acquires New Hospital

The House Committee on Public Buildings and Grounds has approved the purchase by the Public Health Service of the Mount Alto property situated in the suburbs of Washington, D. C. This property will be used for the care and treatment of tuberculous patients. It now has a capacity for 125 beds but it is planned to increase its facilities immediately to 300 beds and later it can be expanded to 2,000 beds. The price fixed by the committee is \$460,000. The property covers 11½ acres and includes nine modern stone buildings. It is considered an excellent unit for hospital purposes. Congressman Tague urged that provision should be made for ample expansion of this property. He said there are 50,000 service men, sufferers from tuberculosis who need immediate attention and that the Public Health Service does not have facilities at the present time to meet the situation. The committee at its next meeting expects to receive a complete summary of the prospective needs for hospital enlargement throughout the country from the Public Health Service.

Public Health Service Requests Additional Funds

Surgeon-General Cumming of the Public Health Service estimates that it will cost the government \$18,316,000 to take care of sick and disabled soldiers and sailors for the fiscal year ending June 30, 1920. In a statement to the Secretary of the Treasury, Dr. Cumming says that the Public Health Service is now caring for 12,000 patients in hospitals and is examining over 3,500 new patients each week. The medical, surgical and hospital requirements of the Public Health Service are such that Congress has been requested to appropriate an additional \$8,816,000 to meet the needs of the service to June 30, 1920.

Bill to Transfer Medical Care of Disabled Veterans to War Risk Insurance Bureau

A bill has been introduced by Congressman Rogers of Massachusetts to transfer to the Bureau of War Risk Insurance the care of discharged sick and disabled soldiers and sailors. This work is now being performed by the United States Public Health Service and is of course only a part of the functions of the latter organization. The care of sick and disabled service men has been an enormous task for the Public Health Service and has reached proportions far beyond all expectations. It is the belief of Congressman Rogers that this work can be more efficiently performed by the Bureau of War Risk Insurance because the duties of this bureau are directed exclusively to ex-service men.

MADRID

Feb. 10, 1920.

The Increase of Mortality in Madrid in December and January

Dr. Lasbesnes, director of the bureau of statistics of Madrid, has furnished some interesting data for THE JOURNAL on sanitary conditions at Madrid during the months of December, 1919, and January, 1920. The highest mortality ever reached at Madrid during the present century is shown. The number of deaths at Madrid is always smallest during the month of September, after which it increases gradually, reaching the highest point in January. This happened last fall and winter; but this time the increase in mortality was so great that it caused much anxiety. In the middle of December, 1919, the number of deaths was very high, exceeding greatly the average for this part of the year. The total number of deaths during this month was 2,803. In the last nineteen years there have only been two months with over 2,000 deaths, namely, January, 1914, 2,074, and January, 1919, 2,124. The average for December had been 1,582, compared with 2,803 of last December and 3,059 last January. The most prevailing diseases were bronchopneumonia, bronchitis, pulmonary tuberculosis, influenza, heart diseases, meningitis and cerebral congestions. This is the third wave of influenza, the first having occurred at the beginning of June, 1918, and the second in January, 1919. In the first two, the child mortality was very low, but not so in the present wave, as one disease alone, acute bronchitis, has trebled the deaths among children. Of 345 deaths from acute bronchitis, 310 were in children less than 5 years old. Typhoid fever also has increased, fifty-eight having died in December, and sixty-two in January. The deaths from colibacillosis, not included in the typhoid reports, were five in December. Typhoid fever came on so suddenly, and became so prevalent, that the physicians felt compelled to call attention to the fact, since the sanitary authorities were silent about the matter. Smallpox, on the contrary, caused only two deaths in the last seven months of 1919. The suppression of this disease is due, as I stated in a previous letter, to the enforcement of compulsory vaccination by the governor of Madrid. Influenza caused 207 deaths in December and 311 in January, and bronchopneumonia, 385 in December and 446 in January. There have also been a few cases of encephalitis lethargica. An important fact, to which Lasbesnes invites attention, is the decrease in the number of births, which have been decreasing slowly but constantly, after reaching in 1917 the highest figure of 17,178 live births; in the last two years, in spite of the increase in population, the births have decreased to 16,958 in 1918 and 16,309 in 1919.

The Physicians of the Franciscan Order

The Third Order of St. Francis has had in Madrid for a long time a hospital, very popular among the thousands of people who belong to that order. In order to become a physician of that hospital it was necessary to take an examination, and the physicians chosen had occupied these places for many years with general approval. The election of a new board of directors caused difficulties among those participating in the work of the hospital. There was an open break, and the physicians, pharmacists and chaplains were expelled without any explanation. The board of directors then appointed two physicians to replace those thrown out so informally. These physicians, however, appealed to the Association of Physicians of Madrid. After many discussions and controversies, a meeting was held, February 6, at which

the evidence presented by Dr. García de la Sarrana, one of the expelled physicians, convinced every one of the injustice committed in their case. Those who had replaced them hastened to place their resignations in the hands of the board of directors of the Association of Physicians. Pending the final decision by the department of the interior, which is now considering the matter, the board asked the new physicians to continue in their places. All considered, this is a new victory for the medical profession, which has shown its solidarity.

Conclusions Based on More than Two Thousand Laparotomies

Dr. Cospedal Tomé, the gynecologist, dean of the Hospital de la Princesa, delivered the inaugural address of the medical course before the Royal Academy of Medicine. His address was a simple presentation of his surgical experiences and technic obtained in many years of constant practice. He favors chloroform anesthesia and the figure of eight suture to close the abdominal cavity, which prevents the entrance of foreign material, and expresses surprise that this kind of suture has not become more popular.

LONDON

March 20, 1920.

Memorial to Osler

A meeting has been held at Oxford to consider what steps should be taken to perpetuate the memory of Sir William Osler. It was attended by many leading members of the university and of the medical profession. The vice chancellor, who presided, said that the meeting was held to show the respect and affection felt for the late regius professor of medicine not only by the University of Oxford but also by other universities on more than one continent and by the London hospitals. Osler's name would always be associated not merely with the history of the chair of medicine at Oxford but with its actual existence as well by reason of the generous benefaction, of which he was the first to hear from Osler's lips. Sir Clifford Allbutt, regius professor of physic in the University of Cambridge and president of the British Medical Association, in proposing a resolution that Osler's distinguished services were worthy of a permanent memorial in Oxford, said that it would be impossible to sum up what made the real charm of Osler's character. He would present only one point of view: the universality of his experience and his sympathies. A resolution was then proposed by Sir William Church, formerly president of the Royal College of Physicians: "That in view of the intimate association of Sir William Osler's life work with Oxford and the study of the origin and prevention of disease, the most appropriate form of memorial would be an Osler Institute of General Pathology and Preventive Medicine." The resolution was adopted. On the motion of the dean of Christ Church, seconded by Sir A. E. Garrod, Osler's successor in the chair of medicine, committees were appointed to issue an appeal. It was announced that a provisional committee of Osler's friends in America, consisting of Professors Welch, Harvey Cushing, Billings, President Butler and Dr. Walter James, had been appointed. Among those who have expressed sympathy with the proposal are the United States ambassador, the British ambassador to the United States, the high commissioner for Canada, and the president of the Royal College of Physicians.

Clean Milk

The supply of clean milk still remains an unsolved problem. Under ordinary farm conditions, fecal and other forms of contamination are rife and in general cannot be prevented. However, the food controller has instituted a system

of licenses by which clean milk can be sold under a guarantee. There are two licenses: "Grade A milk" and "Grade A certified milk." These designations can be used only under the license. Grade A milk is produced under specially clean and hygienic conditions from a herd which contains no cow that has not passed the specified tuberculin test and certain other requirements. While the license is held, every facility must be afforded for taking samples of milk from any cow in the herd or from the mixed milk. The farm must be open to government inspection and must attain a certain standard in equipment and methods. The license is granted only after such inspection, and if later the standard is found to have deteriorated, the license may be withdrawn. The milk must be cooled on the farm and consigned in a sealed container having a label giving the address of the farm, and stating whether from morning or evening milking. Dealers who desire to sell the milk must show that their equipment and methods are satisfactory and that the milk is delivered to the consumer in the vessel in which it is received, or in bottles sterilized by steam, filled on the premises of the retailer and closed by disks or caps showing the day of production. For Grade A certified milk there are additional requirements. The milk after cooling must be bottled on the producer's premises in sterilized bottles and labeled to show the day of production and the time of the day. On examination at any time before delivery to the consumer, it must not contain in 0.1 c.c. (in each of two tubes) *B. coli* or more than 30,000 bacteria per cubic centimeter. Further, the milk must not be delivered to the customer more than two days after production.

The Range of Services of the Panel Physician

The panel physician contracts to render such services as can be "properly undertaken by a general practitioner of ordinary professional knowledge and skill." What exactly this includes would in some cases be a question. A dispute arose between the Glasgow insurance committee and the local medical committee whether the operation of suturing tendons of fingers is a service of a kind which can consistently with the best interests of the patient be properly undertaken by a general practitioner of ordinary skill. The insurance committee contended that the operation did not require special skill. The question was referred to referees, who included Mr. F. K. Smith, surgeon to the Royal Infirmary, Aberdeen. The referees held that a distinction must be made between the operations on the tendons at the back of and on the front of the hand. They pointed out that there were special risks and difficulties in suturing the tendons of the palm. The sheath which encloses the palmar tendons may be the means of carrying septic material into the palm or forearm, and, moreover, the proximal end of the severed tendon, being subject to retraction into the sheath, may involve operative enlargement of the original wound. The conditions existing in the patient's dwelling, under which the general practitioner would generally have to operate, would increase the risk of sepsis, especially when the fingers have been crushed. The referees therefore decided that no general rule could be laid down that suturing tendons of a finger was a service which could properly be undertaken by the general practitioner.

The British Journal of Experimental Pathology

A new journal, for which the annual subscription is \$10, has appeared under the editorship of leading pathologists: C. H. Browning, P. Fildes, W. E. Gye, E. L. Kennaway, E. H. Kettle, J. McIntosh, J. A. Murray, W. J. Tulloch and C. M. Wilson. Among the articles in the first number are: "Is Haemolysed Blood Toxic?" by Professor Bayliss. The author brings forward evidence to show that hemolysis in itself is

harmless. The matter is of great practical importance because of the view that serious results may be due to the hemolysis of corpuscles introduced in transfusion. The experiments on which this view is based have been performed on rabbits. Bayliss points out that rabbits are not suitable animals, owing to their aptitude for intravascular clotting. In the cat and dog, homologous hemolyzed blood is usually innocuous. He regards the occasional ill effects of transfusion as due to anaphylactic shock from foreign serum protein. J. McIntosh and W. A. M. Smart contribute a paper on "The Reaction of Bacteriological Culture Media"; W. Cramer, on "Sympathetic Fever and Hyperpyrexial Heat Stroke"; P. M. Fildes, on "The Serological Classification of Meningococci," and H. Maclean and O. L. V. de Wesselow on "The Testing of Renal Efficiency." It will be seen that a high standard and one representative of the British school of pathology is maintained.

Influenza

Influenza is again prevalent, but so far the cases are neither numerous nor of severe form. The number of deaths registered from the disease in the ninety-six principal towns during a week has risen from forty-three, the lowest in the last thirteen weeks, to 196. The army authorities are investigating the bacteria of all kinds present in the throats of soldiers, so that if an epidemic becomes general it will be possible to determine whether any new microbe appears among the ordinary organisms of the throat.

The Fellowship of Medicine: Osler's Successor

Sir George Makins, president of the Royal College of Surgeons, has become president of the Fellowship of Medicine and Post-Graduate Medical Association, in succession to Sir William Osler.

PARIS

Feb. 26, 1920.

Eight-Hour Day in Paris Hospitals

The eight-hour day, which has been in force in Paris hospitals since the beginning of the year, is giving deplorable results, and the *Journal des Praticiens* contains a bitter arraignment of the system. Among the inconveniences arising out of the new system the most important are: the reduction of the hospital personnel at 4:30 p. m. to one supervisor for four wards and to one nurse for each ward; the disorganized condition of the hospital service between 11 a. m. and 2 p. m. during the time a large part of the personnel are taking their meals outside of the hospital, and the necessity of enlisting the services of a new personnel that is far from satisfactory. The present system interferes especially with the intern on his second round. In order to have an opportunity to do any useful work, the intern should, under the new system, make his second round between 3 and 4 o'clock, which is much too early for him, as he does not leave the hospital after his first round until 12 or even later. Then, again, if he does come at 3 p. m. he breaks in on the taking of temperature, the bathing of patients, etc. On the other hand, after 4:30 p. m. the intern might as well give up making a second round, for the sole nurse in charge of the ward has just come on duty and is not in touch with things as yet; nor is she in a position to accompany him on his round, as she is being summoned every few minutes by this or that patient.

Aside from the disorganization referred to, the eight-hour day has had a bad moral effect on the hospital personnel. Nurses who under the old system did not hesitate to put in a half hour overtime, if it seemed necessary, now make it a point to leave on the stroke of the clock, which works hardship on the poor fellow who is so inconsiderate as to be in urgent need of assistance just at that moment.

The Needs of Paris Hospitals

In his recent report, M. Mesureur brings the needs of Paris hospitals forcibly to the attention of the Conseil de surveillance de l'assistance publique. He states that the small service of radiotherapy as organized in the Hôpital Pasteur contrasts unfavorably with the progress that has been realized in radiotherapy in foreign countries, and is inadequate to supply the needs of poor cancerous patients, who are becoming more and more numerous. M. Mesureur suggests, therefore, that an up-to-date radiotherapeutic service be organized. He also calls attention to the fact that Paris lacks a thoroughly organized service of physiotherapy, and recommends that the need be supplied. Furthermore, he requests that also services in which special attention is given to conservation work and plastic surgery be established in various Paris hospitals; for example, Charité, Salpêtrière, Bicêtre, Saint-Louis, Saint-Antoine, Laënnec, etc. M. Mesureur estimates that the total cost of the proposed improvements will amount to 150,000,000 francs, and suggests that the city of Paris place at the disposal of the Assistance publique the sum of 15,000,000 francs annually for the ten-year period 1922-1931.

Violation of the Right of Privileged Communication

The question of the right of privileged communication came up recently in a French court (Cour de Paris), and the circumstances were these: In support of his demand for a divorce, a husband produced a medical certificate setting forth the pathologic condition of his wife. The court, calling attention to the fact that the right of privileged communication is a matter of public policy, ruled that a physician has not the right, without the knowledge of his patient, to deliver a medical certificate to a third party, even though the third party should be the husband. The judges, therefore, insisted on excluding from the case the medical certificate that had been delivered in violation of the right of privileged communication. The court went still further and gave a decree in favor of the wife, by reason of the grave injury she had suffered owing to the production in court of the medical certificate in question.

International Scientific Relations

The *Presse médicale* recently published a review of a German treatise on experimental bacteriology, over which fact certain medical journals became very much aroused, especially since the work in question took no account of researches and discoveries in the bacteriology of infectious diseases made outside of Germany since 1914. For example, the book is silent on the interesting American researches relative to the classification of pneumococci, and the important French investigations concerning the varieties of meningococci and the causative agents in gas gangrene. The questions may well be asked: Was this really a systematic boycotting of French and American science, as the *Journal de médecine de Bordeaux* asserts? Can the matter not be explained simply by the fact that, during the war, it was difficult for a German bacteriologist to keep abreast of the times and be familiar with French and American researches, just as French and American bacteriologists must have found it difficult to keep up with German publications on the subject of bacteriology?

At the annual meeting of the Académie des sciences, Prof. Léon Guignard referred in his presidential address to the international scientific relations of the future. He set forth somewhat in detail the work of the Conférence académique interalliée which was held in Brussels and which resulted in the definite founding of the Conseil international des recherches scientifiques. The by-laws of the society were drawn up and neutral nations were invited to collaborate if

such was their desire. The Germans and their allies were excluded until such time as they should have furnished their conquerors rightful reparation and the necessary guarantees. The results of the meeting at Brussels had scarcely become known when a group of members of certain academies in neutral countries filed a petition with the learned societies of the allied nations asking them to resume prewar relations with German scholars and scientists. Professor Guignard holds the view that until the German mentality shall have changed "we shall say: we don't know these men; we don't want to know them." But like a true man of science he recognizes the fact that no scholar worthy of the name "should refuse to take an interest in any idea that may be promulgated throughout the world no matter who the author may be, even though it should be his bitterest enemy; but he can take interest in it without coming into personal contact with the author."

An American Library in Paris

The American nation has presented to France the library of English books that was collected in Paris by private gifts during the war. It will constitute a souvenir of the sojourn of the American soldiers in France. At the present time this library, which numbers 25,000 volumes and has a reading room in connection containing journals and periodicals, is located at rue de l'Elysée, 10, and is open daily from 10 a. m. to 10 p. m. (Sundays, from 2 to 10 p. m.). The American and English colonies in Paris have donated considerable sums in order to assure the library's continued existence. The French committee in charge of the library has issued an appeal to all persons interested and has asked for contributions for the upkeep of the library, introducing for this purpose a sliding scale in order to fit the needs and the varying financial conditions of those interested. Participating members may draw one book at a time, annual fee, 10 francs; subscribing members may draw two books at a time, annual fee, 20 francs; contributing members pay an initial sum of 100 francs and make an annual contribution of 100 francs; supporting members contribute 2,000 francs, and patrons, 5,000 francs. Contributions and subscriptions may be sent to American Library Fund, rue de l'Elysée, 10, Paris.

Death of Dr. Henri Triboulet

Dr. Henri Triboulet, physician to the hospitals of Paris, died recently at the age of 56. He was born in 1864; became hospital intern in Paris, and was appointed physician to the hospitals in 1898. His name is closely associated with the prohibition movement. In 1895 he became one of the founders of the Union française antialcoolique, in the interests of which he has delivered numerous lectures every year in Paris and throughout the provinces. From 1903 to 1905 he held the office of vice president of this society, and in this capacity he became especially interested in the establishment of temperance restaurants where no alcoholic beverages whatsoever are sold. In 1905 he published, in collaboration with Drs. F. Mathieu and R. Mignot, a treatise on alcoholism, "Traité de l'Alcoolisme."

Marriages

DANIEL EDGAR ROBERTS, Keyport, N. J., to Miss Julie Hildeborg Bisgaard, at Holmdel, N. J., March 21.

DANIEL GLEN SMITH, Schenectady, N. Y., to Miss Esther Louis Denny of New York City, April 5.

GLADYS EMELIA PATRIC, Los Angeles, to Milan Chabowitch of Ochrid, Serbia, Nov. 13, 1919.

ALVIN POWELL, Oakland, Calif., to Miss Josephine Miller, January 6.

HEDWIG STIEGLITZ to Mr. Hugo Kuhn, both of Cincinnati, March 29.

Deaths

William Martin, Medical Inspector, Commander, M. C., U. S. Navy, retired, San Francisco; Tulane University, New Orleans, 1874; aged 73; who entered the Navy as acting assistant surgeon in 1874, and was discharged, June 30, 1879; was appointed to the Medical Corps, April 14, 1882, not in line of promotion, by special act of Congress, honorable and meritorious service in yellow fever epidemic, Pensacola, Fla., 1874, and New Orleans, 1878, promoted to surgeon, not in line of promotion, Oct. 1, 1890, by special act of Congress, for extraordinary and meritorious service in yellow fever epidemic, Pensacola, 1888, and was retired, Dec. 25, 1893, with rank of next higher grade to that held on active list, after six years and two months of sea service, including service in the Volunteer Navy during the Civil War; on account of incapacity the result of an incident of service; died, April 1.

Francis A. Seymour, Los Angeles; Kentucky School of Medicine, Louisville, 1864; University of Louisville, Ky., 1867; aged 76; acting assistant surgeon, U. S. Army, during the Civil War; formerly associate professor of physiology and later lecturer on general pathology in the Kentucky School of Medicine; for forty years a practitioner of California; once president of the Los Angeles County Medical Association; associate editor of the *Southern California Practitioner*; for five years president of the Humane Society and the Society for the Protection of Children; died, March 20.

John A. Lee ☉ Brooklyn; Yale University, New Haven, Conn., 1897; aged 47; surgeon, lieutenant-commander, U. S. Navy, and relieved from active duty, Feb. 12, 1919; president of the Kings County Medical Society; surgeon to St. Mary's Hospital, and attending surgeon to the Kingston Avenue Hospital, Brooklyn; one of the early experimenters with the roentgen ray; died, April 5, his death being reported to be due to the result of burns suffered while the effects of the roentgen ray were little understood.

Harry Waldo Kimball, Providence, R. I.; Medical School of Maine, Brunswick and Portland, 1891; aged 52; a specialist in dermatology; dermatologist to the Rhode Island Hospital, consulting dermatologist to the Sophia Little City Hospital, and State Sanatorium for Consumptives; dermatologist to the Sophia Little Home; for the last two years surgeon, U. S. P. H. S., Reserve; died, March 27, from erysipelas.

Thomas A. Harris, Parkersburg, W. Va.; University of Virginia, Charlottesville, 1854; aged 89; a member and once president of the West Virginia State Medical Association; surgeon of the Twenty-Third Georgia Infantry, C. S. Army, during the Civil War; for several years a member, secretary and president of the West Virginia State Board of Health; died, February 29.

Jean B. C. Gazzo ☉ Raceland, La.; University of Louisiana, New Orleans, 1879; aged 63; for twelve years coroner of Lafourche Parish, and for four years parish health officer; for one term president of the Louisiana Pharmaceutical Association, and for thirty years local surgeon for the Southern Pacific Railroad; died, March 14, from heart disease.

Leonard St. John ☉ Chicago; McGill University, Montreal, 1872; M.R.C.S. (Eng.), 1873; aged 67; at one time professor of clinical surgery in the Chicago College of Medicine and Surgery; for many years surgeon to St. Anthony's Hospital; one of the founders of the College of Physicians and Surgeons; died, April 2, from heart disease.

Joseph Anthony Mangiaracina, Brooklyn; University and Bellevue Hospital Medical College, New York City, 1917; aged 26; lieutenant, M. C., U. S. Navy, and on duty during the World War, at the Naval Aviation Station, Rome, Italy; a member of the Medical Society of the State of New York; died, February 14, from appendicitis.

Phoebe Thorne Williamson, Brooklyn; Woman's Medical College of the New York Infirmary for Women and Children, 1878; aged 70; founder of the Woman's Hospital, Poughkeepsie, and for many years a member of the staff of the Eastern Dispensary, Brooklyn; died in the Hahnemann Hospital, New York City, March 21.

William Gaertner, Buffalo; University of Marburg, Germany, 1886; University of Buffalo, 1894; aged 59; a member of the Medical Society of the State of New York; since 1914 president of the board of trustees of Grosvenor Library, and

a member of the state board of health from 1900 to 1918; died, March 12, from pneumonia.

Edgar Lee Lindsey, Fort Smith, Ark.; University of Arkansas, Little Rock, 1910; aged 33; a member of the Arkansas Medical Society; lieutenant, M. C., U. S. Army, and discharged on account of physical disability, Feb. 27, 1918; a specialist on diseases of the eye, ear, nose and throat; died, March 8, from pneumonia.

Willard Young Croxall ☉ Hoquiam, Wash.; Jefferson Medical College, 1896; aged 50; a member of the Pacific Coast Oto-Ophthalmological Society, and a specialist on diseases of the eye, ear, nose and throat; died in the Portland Surgical Hospital, March 12, two weeks after a surgical operation.

William Henry Hurlbut, Fond du Lac, Wis.; Eclectic Medical Institute, Cincinnati, 1868; aged 83; for two terms state assemblyman from Walworth County, and for thirty years attending physician to the Walworth County Insane Hospital; died at the home of his daughter in Fond du Lac, March 23.

Harry Neafie Taylor ☉ Maricopa, Calif.; Bellevue Hospital Medical College, 1898; aged 46; president of the West Side Medical Association; city health officer of Maricopa; president of the board of school trustees, and a director of the Maricopa Bank; died, March 3, after a surgical operation.

Aurelius Pallones, Beltzhoover, Pittsburgh; University of Brussels, Belgium, 1886; University of Paris, France, 1887; Jefferson Medical College, 1889; aged 73; commissioned major and surgeon during the war with Spain; for five years on duty with the Ninth U. S. Infantry; died, March 16.

George Williamson Cabaniss, Washington, D. C.; Howard University, Washington, D. C., 1890; aged 62; a colored practitioner; once president of the Medico-Chirurgical Society and visiting physician to the Freedmen's Hospital; died, March 7, from acute gastritis.

George Henry Ensing, Vashon, Wash.; Detroit College of Medicine, 1904; aged 37; who served as captain in the Royal Army Medical Corps during the World War, and was gassed in Flanders; is reported to have committed suicide by drowning in London, about March 21.

George H. Grimmell, Colorado Springs, Colo.; College of Physicians and Surgeons, Keokuk, Iowa, 1877; aged 84; a veteran of the Civil War in which he served as surgeon of U. S. Volunteers; for many years a practitioner of Des Moines, Iowa; died, March 14.

Jacob R. Shel'enberger, Philadelphia; University of Pennsylvania, Philadelphia, 1867; aged 78; a member of the Medical Society of the State of Pennsylvania; once president of the Philadelphia Aid Society for Physicians; died, March 20, from heart disease.

Richard Aloysius Phelan, St. Louis; St. Louis College of Physicians and Surgeons, 1909; aged 47; a member of the Missouri State Medical Association; lieutenant, M. C., U. S. Army, and discharged, Dec. 7, 1918; died, March 14, from malignant disease.

Benjamin Ely Braselton, Miami, Okla.; University of Texas, Galveston, 1899; aged 43; a member of the Oklahoma State Medical Association; captain, M. R. C., U. S. Army, and discharged, March 4, 1919; died, February 9, from pneumonia.

John T. Blank, Elk City, Kan.; Eclectic Medical Institute, Cincinnati, 1890; aged 60; a member of the Kansas Medical Society; while driving his automobile over a grade crossing at Independence, Kan., March 29, was struck by a train and killed.

Henry B. Brown, Lincoln, Ill.; St. Louis Medical College, 1876; aged 68; local surgeon for the Chicago and Alton and Illinois Central systems; and surgeon to St. Clara's Deaconess hospitals, Lincoln; died, March 18, from heart disease.

James H. Bronaugh, Calhoun, Mo.; Missouri Medical College, St. Louis, 1871; aged 81; a member of the Missouri State Medical Association, and a charter member of the Henry County Medical Society; died, January 14.

John Alexander Dickson, Rock Creek, Ohio; University of Wooster, Cleveland, 1876; aged 69; local surgeon of the New York, Chicago and St. Louis Railroad; once president of the state medical board; died about March 22.

Leroy Joe Gillespie, Hope, Ark.; Missouri Medical College, St. Louis, 1886; aged 68; president of the Hempstead County (Ark.) Medical Society in 1893; died, February 15, from pneumonia following influenza.

H. Murray Loewenthal, Brooklyn; College of Physicians and Surgeons, Baltimore, 1892; aged 47; formerly superin-

tendent of the Rubber Plantation Hospital, Elopura, British North Borneo; died, March 13.

Richard B. Graves, Hot Springs, Ark. (license, nongraduate, State Medical Board of Arkansas, 1903); aged 77; for more than half a century a practitioner of Hot Springs; died, March 18, from pneumonia.

George P. Minvielle, Jeanerette, La.; University of Louisiana, New Orleans, 1877; aged 64; a member of the Louisiana State Medical Association; died in St. Mary's Hospital, Patterson, La., March 14.

James R. Champion, Hilldale, Mo. (license, Missouri, 1903); aged 51; a member of the Missouri State Medical Association, and president of the Howard County Medical Society; died, March 8.

Charles Lowndes, Easton, Md.; University of Maryland, Baltimore 1855; aged 87; for six years a medical officer in the United States Navy; died February 24, from arteriosclerosis.

Ralph Gardner Curtis, Hollister, Calif.; Jefferson Medical College, 1901; aged 49; died in the University of California Hospital, San Francisco, March 22, from carcinoma of the lung.

Warren LeRoy Ayer, Owego, N. Y.; Long Island College Hospital, Brooklyn, 1868; aged 76; a member of the Medical Society of the State of New York; died, March 25.

James Edward Greene, Brooklyn; College of Physicians and Surgeons, Baltimore, 1884; aged 58; died in the Macon, Ga., Hospital, March 2, from nephritis.

Wylie Brown, Tucson, Ariz.; Physio-Medical Institute, Cincinnati, 1862; aged 86; for many years a practitioner of Reno County, Kan.; died, March 12.

Hal J. Palmer, Navasota, Texas (license, years of practice, Texas State Board of Medical Examiners, 1907); aged 83; died in Morrilton, Ark., recently.

James William Elliott, Boston; Bellevue Hospital Medical College, 1898; aged 45; died in the Boston City Hospital, about March 4, from nephritis.

Jesse Clark Trueblood ☉ Loogootee, Ind.; Miami Medical College, Cincinnati, 1879; aged 69; died, March 13, from valvular heart disease.

Edward Oliver Brannon, Conway, Ark.; University of Tennessee, Nashville, 1879; aged 70; died, March 11, from Bright's disease.

Lorenzo Erasmus Norton, Fremont, Mich.; Bellevue Hospital Medical College, 1873; aged 71; also a druggist; died, March 21.

Charles C. Curtis, San Pedro, Calif.; Hahnemann Medical College, Chicago, 1874; aged 76; died, March 14, from nephritis.

Fred Carter Newcomb, Akron, Ohio; Cleveland Homeopathic Medical College, 1898; aged 52; died, March 17, from uremia.

Ora Haskell Lamb, Demorest, Ga.; University of Vermont, Burlington, 1874; aged 73; died, January 15, from pneumonia.

Michael J. Lawler, Carthage, N. Y.; Albany, N. Y., Medical College, 1890; aged 52; died, March 7, from pneumonia.

Edward J. Freeman, Freemansburg, Pa.; University of Pennsylvania, Philadelphia, 1873; aged 68; died, March 14.

Herbert Carleton Sawyer, La Jolla, Calif.; University of California, San Francisco, 1881; aged 62; died, March 7.

Eben Bell Kirk, Montgomery, Ala.; University of Alabama, Mobile, 1885; died in a hospital in Montgomery, March 10.

Sumrow Sampson Greene, Vernon, Texas; Vanderbilt University, Nashville, Tenn., 1916; aged 25; died, February 11.

Granville L. Gorslene, Chillicothe, Ohio; Starling Medical College, Columbus, Ohio, 1865; aged 82; died, January 9.

Edward F. Walsh, Philadelphia, University of Pennsylvania, Philadelphia, 1883; aged 58; died, March 17.

Charles Sienknecht, Harriman, Tenn.; University of Nashville, Tenn., 1866; aged 78; died early in January.

Michael Vandervoort, Guthrie, Okla.; Hahnemann Medical College, Chicago, 1868; aged 77; died, March 10.

Benjamin L. Wills, Plant City, Fla.; University of Pennsylvania, Philadelphia, 1864; died about March 9.

Alexander Easley Boyd, Yoakum, Texas; Louisville (Ky.) Medical College, 1888; aged 54; died, March 7.

John Watson Carter, Bessemer, Ala.; University of Nashville, Tenn., 1874; aged 70; died, February 21.

Correspondence

DIFFICULTIES OF SECURING VITAL STATISTICS AND OF REGULATING MIDWIVES

To the Editor:—As an illustration of the difficulties of securing birth and death registration, I am enclosing copy of a certificate of death received at our office, which we afterward found to be due to hydrocephalus, the physician being, as stated, in the war. The spelling is exactly as given:

this deth was from magnesium of the bran the Dr wated on this child is in wor surves.

We also enclose a letter which we have just received from one of our midwives showing the task which we have before us in our effort to teach these women to be safe obstetricians:

Dear Sirs: i an sending for more eye drops i am only got two in the box please send me a bottle of that medecine to give the pacions after the babies is born and send me some blue mas pills to wash my hands in please I wrote to you sometimes ago to send me the papers i havent got but two planks: what is the reason you havent sent them it is time i was getting them in for this year please try to get the medecine and pills here some time in april for i will want them now very soon send me two packages of blanks about what last a year i have only two more pacions every one i have had the doctor with me and he fills every blank i sended in i have had good luck with all my pacions i am asking of you kindly of you please send me a gum coat and boots i go night and day and i have nothing to preteck me from the rain i am not able to get one myself so far send me seven boxes of eye drops nomore at present answer as soon as you get my letter for i an needing them from the midwife

oh please send me 1 bottle of worme medecine."

H— W—, Hume, Va.

To this we answered:

Dear Madam:—We have your letter and are sending you four ampules of eye drops. We do not send them in bottles. You stick a needle in the end of the wax and squeeze the drops out into the baby's eyes.

We do not send the blue antiseptic tablets. We want to warn you, however, against calling them blue mass pills. Blue mass is a medicine which is taken in the month to act on the bowels. These blue flat tablets are rank poison and would kill any one taking them, thinking that they were blue mass. They are to be used, one tablet to a quart or pint of water to bathe the hands and not for internal use. Do not forget that, and do not call them blue mass. It might fool some one into taking them. They are corrosive sublimate tablets. Never, never call them blue mass again.

We do not think these tablets are safe for any one who has no more sense than that. It is much safer for you to get a cake of germicidal soap and use that. You can get it from Miss Quisenberry, who will send you an advertisement for it, or you can get it from a drug store there perhaps.

We are sending you also some blanks. You asked also for worm medicine. We do not furnish that. Are you crazy, or what is the matter with you? Do you think we can send you a gum coat and boots? We are afraid you have not sense enough to do that kind of work and are afraid we will have to take your permit away from you.

Remember that you must never put your finger inside of a patient for any purpose at all. That is absolutely against the law. Do not forget that. Read all the rules on the back of your permit and practice according to them.

In spite of the material that we have to work with, the puerperal death rate was reduced from 497 in 1917 to 333 in 1919. The latter figures, however, will be somewhat increased by delayed reports. This, we take it, means the saving of perhaps 150 lives of mothers, with perhaps as many more infants. This has been done by circular letters, bulletins, booklets and personal correspondence.

W. A. PLECKER, M.D., Richmond, Va.
State Registrar.

NO PHYSICIAN OR SURGEON AS YET IN THE HALL OF FAME

To the Editor:—Soon there will be the fifth quinquennial election to the Hall of Fame. The first took place in 1900 immediately after the funds had been given anonymously for the building of a permanent monument to the men and women who had contributed most to the nation's well-being and culture. According to the constitution it was agreed that at the first election fifty national figures in art, science and history should be chosen, and that thereafter five were to be added every five years.

The method of procedure is such as to allow no question as to the person's eligibility. The senate of the New York University, made up of the dean and senior professor of each of the university schools with the presidents or other representatives of each of the great theological schools in or near New York City, chooses the electors. There are a hundred of these. Every state is represented by at least one man. These hundred men are chosen by virtue of their eminence in some branch of national culture. They fall into seven main divisions: authors, presidents of universities or colleges, scientists, professors of history, jurists, high public officials or men or women of affairs, and editors. Dr. Charles H. Mayo, Rochester, Minn., is one of the electors. When the names are sent in to the senate of the university they are considered on the basis of constitutional qualifications. Not the least important of these qualifications is the one requiring that the nominee must have been deceased at least ten years.

William T. G. Morton, the discoverer of ether anesthesia, was once proposed under Group VII—Physicians and Surgeons—but failed in the election. I hope there will be no barrier to renominating the "inventor and revealer of anesthetic inhalation, before whom in all time surgery was agony."

The next two greatest figures in American medicine and surgery are perhaps Ephraim McDowell and J. Marion Sims. McDowell performed the first rational and deliberate ovariectomy, which he did in 1809, and of course without an anesthetic; his patient living for thirty-two years after the operation. As is well known, J. Marion Sims (1813-1883) gained for himself a national and international reputation by his invention of the speculum as an instrument for the treatment of pelvic diseases in women, and by his perfecting the plastic operation in the vagina for the relief of vesical fistulas.

The nominations must be sent in before May 1. Besides erecting the tablet in the Hall of Fame, the senate of the New York University is now considering collecting the works, where it is possible, of all the men and women who have thus been honored by the nation. They hope in this manner to create a valuable "Americana," open for study and inspection.

While there may be other great physicians and surgeons in the past generations who have so distinguished themselves as to be worthy to be classed with "America's greatest," I venture to say none has surpassed the achievements of Morton, McDowell and Sims. These were real pathfinders in science and added to human happiness and well-being and the glory of the American medical profession.

S. ADOLPHUS KNOFF, M.D., New York.

REQUEST FOR REPRINTS ON RESEARCH IN PHYSIOLOGY, PHYSIOLOGIC CHEMISTRY AND PHARMACOLOGY

To the Editor:—While I was visiting the Medical School of the University of Louvain, last January, the professor of physiology in that institution asked me to help him, if possible, in procuring reprints dealing with American research along the lines of physiology, physiologic chemistry, pharmacology and related subjects, American writers desiring to aid the department at Louvain may address reprints to Dr. A. K. M. Noyons, Professor of Physiology, University of Louvain, Louvain, Belgium.

RICHARD M. PEARCE, M.D., New York.

County Health Administration.—The county government is the only normal and permanent channel through which governmental policies make the individual contact. The county government is the organ of application in health administration.—W. S. Rankin, *Tr. Assn. Life Ins. Presidents*, 1919.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

REMOVAL OF FRECKLES

To the Editor:—The following prescription, written by Hebra, the dermatologist, is recommended particularly for the removal of freckles. This prescription in my hands has not given satisfaction in the treatment of freckles, and I am wondering whether it would be wise to increase the amount of mercury or use another drug. Unna, the Hamburg dermatologist, uses mercury in the same strength.

W. J. O'DONNELL, Buffalo.

PRESCRIPTION

Bismuthi subnitratris	gr. xxx
Sodii boratis	gr. xxx
Hydrargyri ammoniati	3 i
White wax	q. s. ad 3 i

ANSWER:—This prescription will not remove freckles. There is not enough of ammoniated mercury in it even to be irritating to the ordinary skin. Solutions of mercuric chlorid in a strength of from 0.5 to 1 per cent. are used, under medical supervision for the removal of freckles. They cause a dermatitis and exfoliation of the epidermis, and with that most of the pigment. The effect, however, is only temporary at best, and usually not worth the irritation and effort that it costs.

PRONUNCIATION OF DUODENUM

To the Editor:—Will you be good enough to give me the correct pronunciation of "duodenum," giving by proper diacritical markings the sound of each vowel?

ALICE H. MERRITT, San Diego, Calif.

Librarian, Medical Library Association.

ANSWER:—Duodenum is pronounced dew-owe-dee'num, with the accent on the third syllable.

It rhymes with the first three words in the sentence: "You owe freedom to the Great Emancipator."

The first vowel, "u" (yoo), retains the y element to a certain degree, though the sound of the double o in moon is permissible.

The second vowel, "o," is long and is distinct from the first.

The third vowel, "e," is long, and takes the accent.

The fourth vowel, "u," is short.

Some dictionaries mark a secondary accent on the first syllable.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

ARKANSAS: Little Rock, May 11-12. Sec. Regular Bd., Dr. I. J. Stout, Brinkley. Sec. Eclectic Bd., Dr. C. E. Laws, Fort Smith.

DISTRICT OF COLUMBIA: Washington, April 13-15. Sec., Dr. Edgar P. Copeland, the Rockingham, Washington.

HAWAII: Honolulu, May 10-14. Sec., Dr. R. W. Benz, 1141 Alakea St., Honolulu.

LOUISIANA: New Orleans, May 4. Sec., Homeo. Bd., Dr. F. H. Hardenstein, 702 Machesa Bldg., New Orleans.

NEVADA: Carson City, May 3. Sec., Dr. Simeon L. Lee, Carson City.

NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. R. E. McBride, Las Cruces.

NEW YORK: New York, Albany, Syracuse, Buffalo, May 18-21. Assistant, professional examinations, Mr. Herbert J. Hamilton, Education Bldg., Albany.

OKLAHOMA: Oklahoma City, April 13-14. Sec., Dr. J. M. Byrum, Shawnee.

WEST VIRGINIA: Charleston, April 13. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

AMERICAN CONFERENCE ON HOSPITAL SERVICE

The third meeting of the American Conference on Hospital Service was held in the Congress Hotel, Chicago, March 3, 1920, following the annual meeting of the Council on Medical Education. The plans for this meeting were slightly disarranged owing to the illness of the first vice president, Dr. A. R. Warner. The meeting was called to order by Dr. John M. Dodson. Dr. Alexander Lambert, president of the American Medical Association, was elected as temporary chairman. About fifty delegates were present, representing the following organizations: American Association of Industrial

Physicians and Surgeons; American Association of Hospital Social Workers; American College of Surgeons; American Hospital Association; American Medical Association; American Nurses' Association; Association of American Medical Colleges; Catholic Hospital Association of the United States and Canada; Federation of State Medical Boards; Medical Department, U. S. Army; Medical Department, U. S. Navy; National League of Nursing Education, and National Organization of Public Health Nurses.

The first topic for discussion was the need for women trained in the fundamentals of nursing. After considerable discussion, it was voted to refer the whole subject to the Committee on Nursing, the members of which were later decided on.

At the second meeting, held in Cincinnati in September, 1919, it had been planned to establish several committees. The personnel of four of these was named as follows:

Committee on Interns: Dr. John M. Dodson, chairman, A. M. A.; Dr. John M. Baldy, Philadelphia, F. S. M. B.; Dr. Guy M. Cushing, Chicago, F. S. M. B.; Lieut.-Col. L. J. Owen, M. C., U. S. Army, Washington, D. C.; Miss Bena M. Henderson, Chicago, Children's Memorial Hospital, N. L. N. E.; Rev. P. H. Mahan, Loyola Medical School, C. H. A.; Dr. E. S. Gilmore, Wesley Hospital, Chicago, A. H. A.; Miss Edna G. Henry, A. A. H. S. W.

Committee on Hospital Service, Record and Standardization: John G. Bowman, Chicago, A. C. S., chairman; Col. William N. Bispham, M. C., U. S. Army, Washington, D. C.; Miss Mary Wheeler, A. N. A.; Dr. B. F. McGrath, Milwaukee, C. H. A.; Dr. Clarence D. Selby, Toledo, A. A. I. P. S.; Asa A. Bacon, Presbyterian Hospital, Chicago, A. H. A.; Miss Edna G. Henry, A. A. H. S. W.

Committee on Social Insurance: Dr. Otto Geier, Cincinnati, A. A. I. P. S.; Miss Minnie Ahrens, Chicago, A. N. A.; Miss Elnora Thompson, N. O. P. H. N.; Rev. Maurice F. Griffin, C. H. A.; Miss Edna Foley; Miss M. Antoinette Cannon, A. A. H. S. W.

Committee on Nursing: Miss Mary Wheeler, Illinois Training School for Nurses, Chicago, A. N. A., chairman; Lieut.-Col. Floyd Kramer, M. C., U. S. Army, Washington, D. C.; Miss Louise M. Powell, University Hospital, Minneapolis, N. L. N. E.; Rev. M. P. Bourke, Ann Arbor, C. H. A.; Dr. Louis H. Burlingham, Barnes Hospital, St. Louis, A. H. A.; Miss Elnora Thompson, Illinois Mental Hygiene Society, N. O. P. H. N.; Miss M. Antoinette Cannon, A. A. H. S. W.

It was planned to have the next meeting of the conference in connection with the annual session of the American Hospital Association, which meets in Montreal, Oct. 4-8, 1920.

A meeting of the trustees of the conference was held on Thursday, March 4, which was attended by Rev. Charles B. Moulinier, Miss Edna G. Henry, Col. James Glennan, Mr. John G. Bowman and Dr. Harry E. Mock. Father Moulinier acted as chairman.

It was planned to have each organization in membership in the hospital conference present a report at the next meeting outlining its ideas in regard to improving hospital service. These reports will be summarized by a special committee composed of Dr. John M. Dodson, Miss Mary Wheeler, Miss Edna G. Henry, Col. James Glennan and Father James B. Moulinier. It was decided that the fifth meeting would be held jointly with the annual conference of the Council on Medical Education, early in 1921.

Arkansas November Eclectic Examination

Dr. Claude E. Laws, secretary of the Eclectic Board of Medical Examiners, reports the oral and written examination held at Little Rock, Nov. 11-12, 1919. The examination covered 12 subjects and included 120 questions. An average of 75 per cent. was required to pass. Of the 3 candidates examined, 2 passed and 1 failed. The following colleges were represented.

College	PASSED	Year Grad.	Per Cent.
American Medical College	(1876)		86.3
Kansas City College of Medicine and Surgery	(1918)		81.5
FAILED			
Kansas City College of Medicine and Surgery	(1919)		62

Social Medicine and Medical Economics

EFFECTS OF COMPULSORY HEALTH INSURANCE ON THE PRACTICE OF MEDICINE

M. L. HARRIS, M.D.

CHICAGO

At the close of the previous article (March 27, 1920, p. 908), it was stated that the effects of compulsory health insurance on the medical profession would next be considered. This phase of the subject is in a sense a secondary matter. By this is meant that if compulsory health insurance were a good thing, of unmistakable benefit to the people in general, and a distinct step forward in sociological evolution, then the medical profession would have no just cause for complaint, notwithstanding the fact that it might prove harmful to the best interests of the profession itself. The interests of a small class can never be paramount to that of the whole. Any measure which would be beneficial to all classes must necessarily be beneficial to the medical profession, and, on the other hand, a measure that would be harmful to all classes must be harmful to the profession. If a measure, however, is of negative or even doubtful advantage to the general community, then it becomes not only the privilege but the duty of physicians to point out wherein the measure may prove to be harmful to their own interests. In the present instance, the duty is a double one, for the reason that the harm which may be done the profession is reflected, or passed on to the people.

FUNDAMENTAL DEFECT OF COMPULSORY HEALTH INSURANCE

Speaking entirely from the point of view of the physician, the harmful effects of compulsory health insurance do not lie in the fact that a large percentage of the people are compelled to take out health insurance; if that were the only factor in the case, it would be an advantage to the profession, as it would result in many physicians receiving a much larger income than they now enjoy. However, one should not favor or oppose a measure pertaining to the public welfare merely on account of the possible effect which the measure might have on one's personal income. The fundamental defect of the scheme lies in the fact that the major portion of the benefits that the insured are to receive consists of medical services when ill, and the state presumes to dictate the terms of these services, thus placing them on a purely commercial or business basis. A bunch of sheep may be rounded up, sheared and dipped for the scab all alike at so much a head; but sick human beings cannot be successfully treated in that manner. The personal element is a most important factor in the treatment of the sick, and it cannot be ignored except to the disadvantage of both the patient and the physician. Inanimate objects can be dealt with in a purely impersonal manner, and the transaction may be placed on a strictly business basis. Even dumb animals may be handled in this way; but when it comes to intelligent human beings, each one must be handled as an individual. They cannot be bunched together and treated by the job lot.

Compulsory health insurance, wherever it has been introduced up to the present time, has carried with it some form of contract practice. The state agrees to furnish the insured with medical services when sick as part of the benefits to be received for the premium paid. The state then proceeds to contract for the services just as it would for so much coal or groceries or any other commodity, failing to appreciate the fact that medical services cannot be measured by the ton or bushel. There is no other service so individual

and so personal as medical service. The confidence which an individual may have in his physician and which is often a material factor in the treatment of his illness is something which cannot be forced on one, and the personal interest which a conscientious physician has in the welfare of his patient, whether rich or poor, is something that cannot be bought. Anything which interferes with this mutual relationship between patient and physician is detrimental to both. When a patient is compelled to accept the services of a physician in whom he lacks confidence, however, unfounded that lack of confidence may be, there is found to be a failure of that perfect cooperation which is so essential if the best and speediest results are to be obtained. The conscientious physician who feels that he is called on to treat a patient who he knows has come to him only because he is compelled to and not because he wants to, unconsciously fails to give that patient the best that is in him. The finer sensibilities of both parties are offended, and this is frequently manifested on the part of the patient by a tendency to find fault with the physician, to imagine that he is not receiving the care and attention to which he is entitled.

It is characteristic of those who receive something for nothing, or something that they look on as their right, to find fault and to claim that they are being cheated out of their just deserts. And sometimes their complaints are not entirely without foundation, for the physician, blunted by the circumstance of the purely commercial relation between himself and the patient, fails to exhibit to the fullest extent the humane side of his calling. Contract practice tends to give poor service to the patient and to lower the standard of the profession, both of which must be detrimental to the welfare of the people. The patient who doesn't receive the best that medicine offers is defrauded of something to which he is entitled; yet it cannot be expected that the physician who is underpaid, and whose services are disposed of by the state, by wholesale, can give the best that is in him. It has long been observed that physicians who by reason of circumstances, or otherwise, have been forced into contract practice fail to develop medically and are soon found to be behind the times in their work. However altruistic an individual may be at times, there is no question but that a certain amount of self-interest dominates the actions of men. And it is well that such is the case, as otherwise it is scarcely conceivable that progress would be made.

HARMFUL EFFECTS IN GERMANY

That the foregoing statements are not simply an expression of opinion, but are facts founded on experience, is shown by the effects which compulsory health insurance laws have had on the medical profession in the countries in which they have been adopted. In Germany, the birthplace of compulsory health insurance, that large part of the medical profession that lived by the "krankenkassen" was reduced to a low state of scientific development, and for twenty years or more put up an almost continuous fight against underbidding and cheap and inefficient medical service. The physicians had to resort to strikes in order to secure for their work sufficient compensation to enable them to earn a bare living. The services rendered by the "hausarzt" were inferior in quality, yet entirely in keeping with the low compensation received. An underpaid medical profession means an underdeveloped profession. The making of a physician is not like the making of a bricklayer or a baker; when the latter have learned their trade it is only necessary for them to apply what they have learned, and their work is just as good today as it was yesterday and as it will be tomorrow. In medicine it is very different. A physician never fully perfects himself in his profession, as medical science is advancing and he must spend a certain amount

of time and money practically every day in order to keep up with the advancement. There are no union hours for the physician; all hours of the day and night are work hours for him, and if all of his time is taken up in earning a meager living he soon falls so far behind in his knowledge that he is able to render but poor and inefficient service to his patients. Under such conditions, it is evident that not only the profession but also the community must suffer.

For a time much was heard about the supposed wonderful efficiency of the German people; but at last the germanophilic glasses were struck from our eyes, when the true condition at once revealed itself. The assumption by the government of the obligations of the individual as exemplified in one of its phases by compulsory health insurance, in order that the individual might be able to devote more of his time and energy to the building up of the government, brought forth a people devoid of every sense of obligation, moral or otherwise, and this was one of the factors which led to the government's eventual downfall.

UNSATISFACTORY WORKING OF THE SCHEME IN ENGLAND

What was true concerning the harmful effects of compulsory health insurance on the profession and the people in Germany is fast becoming so in England, the last country to adopt a compulsory health insurance act. That the act is not a success in England is evident from the reports that come from that country.

Concerning the subject of compensation for medical services under the insurance act, Sir Bertrand Dawson in the Cavenish Lectures delivered before the West London Medico Chirurgical Society, in 1918, said:

As regards remuneration, justice demands reform. When we consider the exacting nature of the doctor's life, the long hours, disturbed nights, high tension of his work, it is only just he should be so paid as to live a reasonable life without anxiety. That is not so now. Take a doctor who may get £30 a year net for a panel of 350 patients, or innumerable instances of doctors being paid salaries which workmen would reject with contumely. These things must be changed. If only the truth is presented, this cannot be continued. Pecuniary reward goes too much to the man with physical endurance and plausible tongue, and too little to the man possessed of brain and conscience.

In *THE JOURNAL*, Feb. 14, 1920, p. 474, the London correspondent wrote that the panel physicians had demanded from the government an increase of the capitation fee, claiming that the cost of living had gone up so high that they were unable to get along on the present small capitation fee. A small advance was offered by the government, which the deputation felt bound to its constituents not to accept, and asked for arbitration. The government yielded to the demand for arbitration, but said that it reserved the freedom to institute an inquiry into the question of whether services as good or better could be secured with the same or less expenditure of money under some other system. This is a fair illustration of what contract practice means under government control. The government by the minister of health felt constrained to yield to the demand of the panel (contract) physicians for arbitration of the question of the capitation fee, yet at the same time it reserved the right to see if it could not secure the same services for less money under some other system. Any system that could be devised must include the physician, and if the physician is unable to earn a decent living under existing fees, how could the government expect to get the work done for less money without still further reducing the income of the physician or the amount and character of the medical services rendered? Under the former plan the physician would have to suffer, and under the latter, the patient.

Again, in *THE JOURNAL*, Feb. 28, 1920, p. 615, the London correspondent stated that the minister of health "received a deputation from the British Federation of Medical and Allied Societies with regard to the national insurance act. The deputation came to emphasize the fact that national health

insurance did not permit the insured persons to receive all that the science of medicine had to give, and under the regulations the physician was not able to do the effective work he was willing and anxious to do. . . . The insured public asked for bread and were given a stone. They asked for health and were given regulations which seemed to be chiefly designed to catch the erring physician in some fault. The tendency of the regulations was to impair the efficiency of the health services. . . . The deputation suggested a public inquiry into the working of the act." Does this sound good for compulsory health insurance, when the insured ask for bread and are given a stone, when they ask for health and are given rules and regulations? Do the American people want to introduce into our free form of government a compulsory measure of that kind? Does the medical profession want to place itself in a position in which it must beg the government to permit it to earn enough to live on, or in a position in which the ability to earn a decent living depends on the question of physical endurance rather than brains and conscience? What hope is there for the advancement of medicine when stifled by such laws?

IMPROBABILITY THAT THE SYSTEM WOULD WORK BETTER IN THIS COUNTRY

Any person practicing as a vocation a profession, such as medicine, which requires one to spend so much time and work trying to keep abreast with the progress constantly being made, must possess individualism and freedom of thought and action if he would satisfy his own conscience and bring to his patients the kind of service to which they are entitled.

Contract practice, which has been a part of every compulsory health insurance act up to date, operates in opposition to the physician's success, both from his own point of view and from that of the patient. It is claimed, however, by some of those who favor compulsory insurance that we in America will profit by the mistakes made by those countries that have already adopted such laws. That some of the bad features contained in the acts already in operation in some of the foreign countries might be eliminated seems probable; but it is highly improbable that any system of compulsory health insurance can be devised in which the conditions of medical service and the compensation therefor are under state supervision and control which would not be detrimental to individual and collective medical progress. That the income of a few might be augmented by an insurance act is quite likely; but, as often stated, it is not the advantage of a few but the good of the whole that must be considered. One frequently hears the remark that compulsory health insurance is bound to come sooner or later, just because it has been introduced in other countries. One might as well say that bolshevism or anarchy or Mohammedanism are bound to come, just because they came to other countries. Nothing of this kind is bound to come to a free country that is not the will of the people. The psychologic effect of the frequent repetition of such foolish statements has often led people to do that which they would not have done had they been governed by reason. This is one of the occasions when action should be guided by sound reason and not stamped by psychology.

An attempt has been made to present the subject of compulsory health insurance in an impartial manner. If it has been shown that the scheme is not a desirable one, from the point of view either of the public or of the physician, there still remains an important problem. This problem concerns the best method of providing the highest type of medical service to all persons at prices within the reach of all. It is a problem which should be solved by the medical profession itself.

Book Notices

HEART: PAST AND PRESENT. By Edgar Lea, M.D., M.R.C.P., Assistant Medical Officer, Manchester Royal Infirmary. Cloth. Price, \$2.50. Pp. 300. New York: William Wood & Co., 1919.

This is a readable collection of thoughtful essays on heart disease. Nearly a third of the book is devoted to a historical review of cardiology. The development of various views concerning the heart, from the time of Harvey to the present, is briefly set forth by one who is evidently conversant with the subject and who has read and studied Corvisart, Laënnec, Stokes and others, not alone because he thus acquired an important background of knowledge but because he has the pure delight of the bibliophile in reading the authors of the past. Possibly the still fresh war memories may account for the omission of some German and Austrian names like those of Virchow and Skoda, for example; we are sure it is not lack of knowledge. The present status of cardiology is clearly set forth and there is a systematic discussion of the problems that confront us today. Emphasis is laid on the necessity of a more careful study of symptoms and signs and a not too implicit reliance on laboratory methods and instruments of precision. In this way a more accurate diagnosis or prognosis may be attained and a more rational therapy achieved. The work is not intended as a textbook. It is, as the author states, a plea for a more intensive clinical study of the heart. As such it will be found interesting and stimulating.

PRACTICAL PHYSIOLOGICAL CHEMISTRY. For Indian Medical Students and Clinical Assistants. By C. C. Caley, M.B., M.S., Professor of Physiology, King Edward Medical College, Lahore. Cloth. Price, 6 rupees net. Pp. 252. Calcutta: Butterworth & Co., 1919.

While intended as a laboratory manual for students in physiologic chemistry, this book has some advantage over many other laboratory manuals on the subject in that it is sufficiently complete to be of practical value to the clinician. The commonly used analytic methods are described, the relations of chemical findings to diagnosis are briefly explained, and other useful information is given in a condensed form. The physician who occasionally makes analyses of the body fluids or excretions will find the book helpful.

YOURS FOR SLEEP. By William S. Walsh, M.D. Cloth. Price, \$2.50 net. Pp. 274. New York: E. P. Dutton and Company, 1920.

While not any too scientific, this is a practical book; the author has written a common-sense statement concerning insomnia. Since untroubled sleep presupposes a healthful body and a healthful life, his book resolves itself into a manual of personal hygiene. The final chapter, "Remedies for Sleeplessness," presents no new fad or fancy, but is a sensible discussion of simple time-tried and effective methods. The book can be recommended to sufferers from insomnia, who should read it during the day and not in bed, just before going to sleep. It is not a soporific.

PRINCIPLES AND PRACTICE OF PHYSICAL DIAGNOSIS. By John C. DaCosta, Jr., M.D., Fourth edition. Cloth. Price, \$4.75 net. Pp. 602, with 225 illustrations. Philadelphia: W. B. Saunders Company, 1919.

In this edition, new matter concerning gas edema, gas pneumonia, influenzal pneumonia and hilum tuberculosis appears under the discussions relative to the lungs and the effort syndrome. New material on the functional capacity of the heart, aviators' heart and sino-auricular block appears under the heading of "The Heart." The clinical relation and physical signs of cecum mobile are dealt with in detail. The book is a standard text of merit.

Kingsport, Tenn., a Rival of Framingham.—Kingsport is starting out to be another "health town," and also under the general supervision of the Metropolitan Life Insurance Company. Periodic physical examinations will be made and follow-up of defects and impairments. Results in these two towns will be compared.

Medicolegal

"The Great Exorcism" and Mental Healing

(*Crane v. United States (U. S.), 259 Fed. R. 480*)

The United States Circuit Court of Appeals, Ninth Circuit, in affirming a judgment of conviction of defendant Crane, says that he was convicted under fifteen of twenty counts for having devised a scheme and artifice to defraud, and to obtain money and property by means of certain false pretenses, and promises, and by means of hypocritical doctrines written and advocated by him, and of using the mails of the United States in carrying out the scheme charged. It was alleged that he was the author of books and other kinds of literature and letters and advertising matter in which he attributed all human suffering, physical or mental, to certain mysterious influences, and that he represented that he possessed supernatural powers, with power to save victims from the influences. The literature was alleged to set forth that the defendant could be called on by night or by day by any one desiring treatment, and the method of treatment was that the party being treated should relax, breathe deeply, and with every outgoing breath say that he was unloading all his care on Arthur Crane; that the party receiving treatment was to take the position that he was breathing out all of his own opinions, desires, and all of his knowledge and possessions, that he knew nothing, owned nothing, wanted nothing and believed nothing; that he was not to resist any unpleasant or evil thought that came to him, but was to let the said Crane do all of the resisting for him, and that he was to know consciously that he was calling Crane and breathing in his alleged perfect vitality and harmony. Before relaxing, the party receiving the treatment was to write to Arthur Crane and tell him the time which he desired for his treatment; that when the treatment was given the party receiving it must accept it freely and with the idea of being benefited without rendering any return to the defendant, who represented that he transmitted the "Christ power," and administered for good and not for profit from the sale of his books. To one man he wrote: that he had answered all of the "problems" in the new \$2 edition of his book, "The Great Exorcism," which contained, "among other good things," instructions for healing and relaxing, and which was well worth \$5, and continued: "So if you will send me \$1 toward its price I will give you credit for the \$1 you sent before, and mail you the \$2 book complete. Because I have answered your particular problems in this edition, I feel it is absolutely vital to you to have a copy." Some of his letters referred to money to be sent for treatment as not the defendant's money, but money that must be sent as a gift for his aid in casting out "influences." It was also in evidence that in some of the literature the defendant said he would not charge for his treatments, but the evidence was that in several instances, when a subject or confiding person sought his advice, he would speak of the sacrifice to be made, and then would ask for such giving as the sacrifice warranted. A former employee testified that the system with which the work was carried on was that, after the party had become engrossed in the work, and it was time for a sacrifice, that is to say, if the party had stuck it out long enough and had a proper disposition, he was sure to get a "sacrifice letter." It was elaborately argued that there is "nothing inherently wrong in the theory of mental healing." In a general way that is conceded. The law, however, prohibits a scheme or artifice to defraud by means of false representations, and the use of the mails in executing the purposes of the scheme. One with corrupt purpose may devise a scheme to defraud by employing an alleged mental power to relieve suffering of mind or body, and may use the mails to carry out his corrupt scheme. From the voluminous record containing letters, circulars and oral testimony, it was very clear that the court properly submitted to the jury the question whether the representations made by the defendant were fraudulently

and intentionally false, or were honestly made, or mere errors of judgment. One witness testified that he submitted to treatment for nearly two and one-half months; that sometimes he would go to sleep after treatment and have horrible dreams, such, for instance, as that a she-devil had set a cancer in his legs, and it commenced to eat up his legs past the ankles. He said that he wrote to Crane that he thought the "queen of hell, one of his characters, had charge of the switch board," and that he didn't want any more treatments from him; that the book "The Great Exorcism" described thirteen devils; that the descriptions in the book concerning the various devils upset the witness.

Prescribing and Furnishing Narcotic Drugs Under Minnesota Law

(*State v. Whipple (Minn.)*, 173 N. W. R. 801)

The Supreme Court of Minnesota, in affirming a judgment of conviction of the defendant, a licensed physician, of the violation of Chapter 260 of the Laws of Minnesota of 1915, prohibiting the sale of narcotic drugs, says that the particular charge was that, Jan. 21, 1918, the defendant sold 6 grains of morphin to one Chandler, who was a habitual user of the drug. The defendant admitted that, on this date, he gave to Chandler 6 grains of morphin, and received \$4 from him; but he claimed that he had been treating Chandler since September, 1917, for the drug habit by the gradual reduction method, and that this transaction was a part of such treatment. The evidence on the part of the state was that the defendant sold the morphin to Chandler without any pretense of professional treatment. The trial court instructed the jury that, under the statute, physicians are not permitted by law to sell or furnish to habitual users, out of stocks kept on hand for any purpose, these habit-forming drugs; that all sales and deliveries of such substances to victims of the habit, whether for the purpose of curing the habit or any other object, must be made, if at all, by a pharmacist or druggist, and by him only on a physician's prescription, under the safeguards imposed by law in respect to such sales; that the question whether this particular drug was administered or furnished in good faith or not was not material, and that the statute makes a distinction between the disposal, prescription and furnishing of these drugs to habitual users and to ordinary patients. In the case of patients not addicted, a physician is permitted in the usual course of his practice to prescribe them and also to furnish them. As regards habitual users, the statute first prohibits anybody from either furnishing or prescribing the drug to that class of people. But that is qualified by the permission, in the case of a physician, who in good faith has an addict under treatment for the cure of the habit, to give him a prescription on which he can procure the drug. The physician is forbidden, however, by this statute to furnish the drug himself. The supreme court thinks that the trial court correctly construed the statute. There is a plain difference between "prescribe" and "furnish." To "prescribe" is to give medical direction, to indicate remedies. To "furnish" is to supply or provide. This is the ordinary meaning of these terms. Both words are used, obviously with this distinction as to meaning, in the federal narcotic law of 1915. The context makes plain the intention so to use the words in the Minnesota statute. It was the purpose to require two persons to be concerned in the supplying of narcotic drugs to addicts under the conditions as to publicity which the statute requires in the case of prescriptions. In view of the strict requirements of Section 1, as to the record to be kept by a physician administering the drug to a patient not an addict, it is quite inconceivable that the legislature should have intended that a physician might furnish the drug to an addict without any safeguard or provision for record at all. It was competent, too, for the state to introduce evidence of other sales of morphin to Chandler and of the sale of morphin to other drug addicts, in violation of the statute. Evidence of this character is admissible if it is part of one plan or scheme carried on by the defendant wilfully to violate the law, or if it tends to show an inclination or predisposition to commit the offense charged.

ANNUAL CONFERENCE ON PUBLIC HEALTH AND LEGISLATION

Held under the auspices of the Council on Health and Public Instruction of the American Medical Association, March 4, 1920

(Concluded from page 975)

Health Education in the Public Schools—Twenty Years' Experience in Michigan

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich.: The State Board of Health of Michigan was the second state board of health provided for in this country. The first was in Massachusetts. It is interesting to know that the creation of the Michigan State Board of Health was due to the large number of accidents from the explosion of kerosene lamps, and the discussion at that time about arsenical paper.

In 1865, Villemin, a French army surgeon, experimented with transmission of tuberculosis. On the work of Villemin published in 1868, the Michigan State Board of Health started to preach to the people of Michigan that tuberculosis was a transmissible and preventable disease. It did so by holding sanitary conventions. We started out with four conventions a year, each one in different parts of the state, teaching that tuberculosis and various other diseases were transmissible and therefore preventable.

In 1895 a bill was framed and passed by the legislature compelling teaching on the manner of transmission of disease in every grade in every school in Michigan, from the primary grades to the university. I think the passage of that law was the most effective work we ever did. This bill was modified in 1897, and is now a fairly effective law. In 1915 the legislature allowed us by a unanimous vote an appropriation of \$100,000 to continue demonstration work in tuberculosis in Michigan. We have had a relatively low death rate from tuberculosis; we are going to have a higher

death rate because many of our cities are being crowded, especially the larger ones, by an ignorant foreign population. Our death rate has been about one half of what it has been in the New England states, but that is not altogether due to the educational movement. In this work it is essential to reach the children.

Health Education and Activities in Colleges and Universities

DR. JOHN SUNDWALL, Minneapolis: A university health service is concerned with physically sound students—both in the attainment of positive health and in the continuance of this health during the academic and postacademic life. Related activities of a university health service are: protection of the sound student from communicable diseases; detection, isolation, and provision for the treatment and care of all students suffering from communicable diseases; advice, treatment and, when necessary, care of all students who are ill; early detection and correction, so far as possible, of beginning bodily disorders, such as the degenerative diseases, and correction, so far as possible, of defects in subnormals by advice regarding proper exercise and right living and, when advisable, by treatment. These objects are reached through the personal division of a university health service. The division of sanitation must concern itself with sanitary conditions both on and off the campus. Campus buildings, rooming houses and boarding houses must be inspected and regulated so far as possible. Finally, the health service should accentuate the required hygiene instruction by practical application to student life, and by additional educational methods, such as bulletins, posters and placards relative to health promotion and disease prevention, "patent medicines," etc.; and by use of the student daily paper and other publications in dissemination of health information. Through properly conducted work in physical education, through a required hygiene course, through health services and through medical schools and schools of public health, our colleges and universities can educate the citizens and train the health leaders of our country, thus assuring for the future the national health and vigor fundamental to national security, growth and permanence.

Health Education: A Function of Municipal Health Departments

DR. HAVEN EMERSON, New York: In order to carry out education, one must have something to say and some one to say it to, and a susceptibility or receptivity in the audience appropriate to the matter in hand. Certain groups may always be considered as educable in health subjects: children because of their age; mothers because of their children, and the sick and their immediate associates because of their temporary need. Beyond school age, the interest in health for most adults is a negative quality and cannot be relied on to provide an audience for the written or spoken word, except under pressure of fear, selfishness in self-protection, or self-interest in the betterment of employees.

In the United States, with rare exceptions, health education cannot be applied to the population of whole states without risk of inappropriateness, because of the striking dissimilarity in geologic, geographic, racial, educational, occupational and morbidity setting of the groups to be reached. Health is personal. Health education must be personal, as nearly as conditions permit. The nearer the government is to the lives of the people, the stronger will be public interest in the quality of its public servants. Without health education a community is ill served by its civil government. The municipal government is entitled to the strength which public interest will give to its health administration. The public is entitled to the kind of information which is as nearly personal and appropriate to the local unit, the household, the family, as can be attained. Health education is and must always be a function of municipal health departments.

Health Education: A Function of State Departments of Health

DR. W. S. RANKIN, Raleigh, N. C.: From the point of view of a state department, health education has to do largely with the adult population. The state health depart-

ment, if it would be successful, must constantly strive to disseminate knowledge of health, and in such a manner that the public which it seeks to serve is sufficiently interested to make use of the knowledge imparted. The success of a health department may be definitely measured. Is the death rate reduced? Is there less sickness from preventable diseases? The answer to these two questions shows the value of the public health work done. If the answer is to be affirmative, the people must be reached with the message of health and disease prevention. Present efforts toward health education by state departments of health are heavily handicapped by the expense involved. Appropriations for health departments vary greatly. Some receive barely sufficient to maintain an office and carry on merely the minor duties of such a department. There is much lost motion and duplication of effort. Each state department is attempting to do what the others are going. The result is an unnecessary increase in personnel, a waste in time and money, and less effective methods. The solution is standardization and centralization of a large part of this work. Methods of health education may be divided into those applicable to all states and which therefore should be standardized and centralized, and those which deal with individual state problems.

The most important are the methods by which personal hygiene may be taught to the individual. There are two methods of educational work that must continue largely a product of each state and which must possess individuality, as each would lose in proportion as it became stereotyped in form or lacking local color. These are the monthly health bulletin and the press service, both of which are utilized by nearly every health department of the country. A health department must recognize health education as a primary function. The means of performing this function are many and varied. To get the best possible results, no single department can hope to utilize effectively all the means which are at hand. There must be cooperation, which will standardize materials and eliminate much of the present expense and lost motion.

Health Education a Function of the Federal Government

DR. CHARLES F. BOLDUAN, Washington, D. C.: There is a limitation to the activities of the federal authorities. We should devote a great deal of attention to health education among schoolchildren and adults, but should not concentrate on children alone. Childhood impressions are very lasting. A large part of our program should deal with the education of schoolchildren so far as the work of the federal departments is concerned, and this field will come largely under the United States Bureau of Education, a department of the interior. The Public Health Service should be a national clearing house for all matters relating to public health education, and should maintain a supply depot in which can be collected pamphlets, exhibits, etc. We might establish and operate a bureau of information on health administration which would have on hand information concerning administrative methods in all the various states and communities, so that the health officer would not have to send out questionnaires, but would have this material at hand. The Public Health Service in the past has done some work along that line. We published some years ago a digest of health laws enacted by state and local health authorities, and in that way we tried to meet a part of the need, but that has only been going on in a small way. Another activity we can undertake is the preparation of material for a standard monthly health bulletin. At present there is an enormous duplication of effort there. Another activity is the preparation and publication of a health column in our newspapers. For the last six months we have been doing this, and it has proved of great value. In connection with this health column we conduct a question and answer feature. The number of questions that come in is surprising. Still another activity would be the preparation of press bulletins of family interest. If you can send newspaper material in the form of stereomats they will use them. These stereomats are inexpensive. The Public Health Service should maintain a photographic department so that we can supply to state and local health officers pictures with which to illustrate various phases of

health work. We should also maintain a motion picture department, which is one of the great needs at the present time.

DISCUSSION

DR. JOHN M. DODSON, Chicago: As to the question of rejections in our selective service experience, referred to by Dr. Sundwall, I do not think the percentage of rejections when analyzed at all demonstrates that we are a degenerate nation physically. On the whole, it was a respectable showing. While it is true that many of the causes of rejection were due to lack of proper hygiene and sanitation, if we had only had universal military training, or universal physical culture which goes with military training, we should have escaped most of these fallacies.

As chairman of the Subcommittee on Health Problems in Education, cooperating with the National Education Association, I feel that our hope for the future largely lies in the education of the young. Personal hygiene is a matter of habit. Habits are formed early, and once formed they are not easily broken or changed. Therefore, our hope for the future and for permanent good lies in the education of the children and the inculcation in them of proper habits. For this reason I think one of the most worthy things that this Council on Health and Public Instruction has ever done was when, at the Los Angeles session in 1911, it approached the great body of public school teachers in this country (the National Education Association) and enlisted their keenest interest in health problems in the public schools.

PROF. W. B. OWEN, Chicago: We have reached a most opportune time for the introduction of health education in schools. The war has made us consider very carefully the content and material of our education. If the war had gone on longer, there would have been left in our educational progress some of the things that were coming in very rapidly, and each one different because of lack of cooperation and support, or the withdrawal of leadership of the national government. One of these is food. The food administration put into the schools a course on foods, and it is a great pity that it was stopped. They had the material in such form that it could be used, and the teachers were learning how to teach it, and the children were interested in it, and it went from the schools to the homes and from the homes back to the schools. The evidence is undisputable. Every one is coming to recognize that one of the fundamental new objectives laid down in our public education is health. Every one is trying to put thrift into the public schools at the present time. Buying economically and intelligently is a vital question, and if you combine the matter of selecting foods for health purposes, one can readily see how the whole thing would work together in a common program. In order to do this we must have the assistance of competent people to lay out a course and teach this course to teachers who are going to go into the schools.

DR. W. E. FORSYTHE, Ann Arbor, Mich.: The development of health service in colleges and universities is like other phases of public health work of recent origin. Some of the older universities, like the University of Virginia, have been taking care of their students' health for many years. The University of Virginia is probably the oldest in the development of a well-rounded service for the health of its students. The University of Michigan started this movement in 1913. We first began to care for sick students, and I regret to say that has been the main work in most places. Now attention in health matters is given to the well. There is difficulty sometimes in convincing the deans of various departments that this is important, so that we have to educate our educators in this work in our institutions. It is encouraging to have this program adopted for secondary schools, as it will stimulate our higher educational institutions to prepare teachers properly to meet this need. The great help we have had has been cooperation of the governor in the work of the Interdepartmental Social Hygiene Board.

DR. BURTON D. MEYERS, Bloomington, Ind.: We organized a department of hygiene in the Indiana University last year under the auspices or support of the United States government. We have had a required course for freshmen for about ten years, and it has been of tremendous value in developing

better health conditions. We require those training for the teaching profession to take lectures in hygiene and work in physical training.

DR. JOHN DILL ROBERTSON, Chicago: We have in the public schools of Chicago little mothers clubs in which pupils of the sixth, seventh and eighth grades attend lectures on the rudiments of home nursing and public health work. A large part of the publicity of printed material is wasted. It never goes over, and a great deal of the lecture work never goes over. We have what we call the Chicago Public Health Association. Students of the sixth, seventh and eighth grades are required to attend seventeen meetings each month. In order to be sure that the students grasp the lectures, a digest of each lecture is handed to the pupils as they pass out the door, and they write an essay on it and present it to all the pupils in their rooms. We have established a Chicago Training School for Home and Public Health Nursing, and since August, 4,000 Chicago housewives have attended this course. It was done primarily for the purpose of preparing women to take care of sick people in times of an epidemic, such as influenza or pneumonia. About the time the epidemic of influenza started we had 2,160 who had attended the course of forty-eight lectures. We also established a public health education course, and 3,046 women have now some conception of what we are trying to do in health education work.

DR. HAVEN EMERSON, New York: I have been responsible since October for one of the things developed in the Interdepartmental Social Hygiene Board, a compulsory course in hygiene attended by 2,500 students of Cornell University. The students attend these lectures once a week. They have two medical examinations. This is required of all students in the university throughout the year or short term. The education that comes from medical examination and conferences or consultations is of more value than didactic teaching.

COL. JAMES C. GREGORY, Chicago: In reference to what was said about the draft examination, of approximately 4,000,000 men examined, about 60 per cent. had physical defects. Had these examinations been made by thoroughly trained men, more defects would have been found. Twenty-nine per cent. were rejected, and of that 29 per cent., 39 per cent. were rejected for mechanical defects, such as flatfoot, hammer toe, hallus valgus, deformed fingers and stiff joints. A large percentage of these difficulties could have been remedied had the men been examined and properly treated during their younger days. Ten per cent. of the rejections were due to undeveloped and metabolic conditions, narrow chests, under height, etc. Ten per cent. were due to sensory disturbances, such as defective hearing, defective vision and conditions of the throat. Three per cent. were rejected as a result of deficient or defective teeth. Ten per cent. of rejections were due to cardiac disturbances. A large number of these cases of cardiac disturbance were the result of defective teeth and enlarged tonsils. I do not see any better way than to start with the schools and with lectures from the teachers to the children, teaching them the elementary principles of hygiene, how to keep themselves healthy, and to grow up as physically fit as possible.

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich.: One of the most instructive things that came out as the result of the examinations of men during the war is the distribution of the unfit. Pennsylvania, with its large foreign population, had a much larger percentage of unfit than Alabama or Georgia, with a large negro population; in other words, the negro is more fit physically than the average man in Pennsylvania.

DR. W. F. DRAPER, Washington, D. C.: The Public Health Service, in cooperation with the State Board of Health of Virginia, made an arrangement with counties in which no previous health work has been done, whereby the county pays \$1,000 and receives \$1,000 from the state for a full-time sanitary administrator, who takes up the problems relating to rural sanitation, proper disposal of waste, proper protection of water supply, etc. We are trying to secure three results; namely, to have the towns sanitized; to get sanitary toilets, and a pure water supply in every county, and to reach as many homes as possible. The results of this work have been very gratifying.

*Camphor Oil Tumors. W. H. Mook and W. G. Wander, St. Louis.—p. 304.

Causes of Reactions Following Intravenous Injections of Arsphenamin and Neo-Arsphenamin.—The ingenious theory advanced by Danysz that intravascular precipitation of the organic arsenicals is the cause of the reactions (particularly the nitroid reactions) after intravenous injection, the authors claim, is true in part only. It explains the well known precipitation of solutions of acid arsphenamin and probably also concentrated solutions of monosodium arsphenamin (i. e., arsphenamin neutralized to the point of clearing). There is no adequate evidence, however, that precipitation occurs after the use of disodium arsphenamin (hyperalkaline solutions), and there is no evidence at all that neo-arsphenamin is ever precipitated in the blood. Experiments carried out by Schamberg et al. indicate that the phosphates of calcium, magnesium, sodium and potassium in the concentrations in which they normally occur in the blood, do not precipitate alkaline solutions of arsphenamin and neo-arsphenamin in vitro, either when tested alone or in the presence of the other organic or inorganic constituents of the blood. They believe that if arsphenamin is properly neutralized, that is, if the disodium and not the monosodium arsphenamin is injected, precipitation in vitro can scarcely take place. The fact that arsphenamin is hemolytic in practically all of the concentrations in which it is employed, and that neo-arsphenamin is not hemolytic, except in very dilute solutions (0.9 gm. in 180 c.c. of water) or in extremely concentrated solutions (0.9 gm. from 2 to 3 c.c.) sheds a degree of illumination on the relative manner in which these drugs are clinically tolerated. Another fact of importance is the hydrogen-ion concentration of these two compounds. The hydrogen-ion concentration of neo-arsphenamin is 7.0 to 7.4, which is approximately that of the blood. That of acid arsphenamin is 4.7, while the alkaline solutions are beyond 9. The injections of acid solutions of arsphenamin are prone to produce death, or if less concentrated, may lead to the development of a bronchopneumonia as a result of intravascular precipitation of the drug. Concentrated monosodium arsphenamin solutions may, under certain conditions, likewise cause death, or in the event of recovery cause an embolic bronchopneumonia. The authors have no knowledge that pneumonic symptoms have ever developed after the use of disodium arsphenamin, nor after the use of neo-arsphenamin. Nitritoid reactions may, at times, follow the injection of a clear solu-

tion of neo-arsphenamin. The authors believe the cause to be traces of an unidentified impurity which for purposes of convenience and easy reference they designate substance X.

Neurotic Excoriations.—The term neurotic excoriations is limited to traumatic lesions produced by a person without intent to deceive. At times, the excoriation may be produced by the habit of picking at every slight elevation of the skin. This picking or digging may be quite unintentional and, in mild cases, it is limited to an unconscious habit of passing the hand over the face (and the scalp, if bald) while deeply absorbed in study, locating a little follicular plug and digging with the finger nail until an excoriation is effected. In the same way, the reparative crust is repeatedly removed, healing is retarded and the lesion may persist for weeks or months, becoming, perhaps, indurated or infected, and finally, when left alone, disappearing spontaneously, often with scar formation. The question of diagnosis—differential diagnosis—is important. The illustrative cases reported by MacKee show that neurotic excoriations may markedly simulate syphilis, tuberculosis, radiodermatitis, dermatitis herpetiformis, acne varioliformis, and other dermatoses. Care also must be taken to differentiate clearly between neurotic excoriations and malingering, and to exclude excoriations produced in attempts to relieve severe itching by individuals who are not neurotic.

The cases reported by Pusey and Seneear, are essentially of the same character as the cases of neurotic excoriations reported by Fox and Wilson.

Veneroid Ulcer.—Veneroid ulcer or the ulcer of Welander is a disease characterized by the appearance of ulcers about the vulvae of girls or women who have not been exposed to venereal disease. The general appearance of veneroid ulcer is strikingly similar to that of chancre and chancre. The disease is self-limited, healing under indifferent treatment in about one month. The scars left after healing are typical. They are superficial, round or oval, with slightly raised edges. Olson reports one case.

Idiopathic Hemorrhagic Sarcoma.—Two cases of the idiopathic hemorrhagic sarcoma of Kaposi are reported by Cole and Crump, occurring in a Russian Hebrew, aged 66, and in an Italian, aged 56. In the first case, the disease was of five or six years' duration; in the other case, of twenty years' duration. In Case 1, the patient developed a lymphatic leukemia in the course of his disease, but throughout the disease his cutaneous lesions showed the histologic characteristics of hemorrhagic sarcoma of Kaposi; i. e., the formation of new blood vessels in the corium, perivascular infiltration with small, round cells, plasma cells and spindle cells, and with a marked infiltration of the tissue with blood pigment, consisting of hemosiderin. Experimentally, the authors were unable to transmit the disease to cats, white rats, to guinea-pigs and to rabbits.

Camphor Oil Tumors.—The six cases reported by Mock and Wander seem to indicate that it is dangerous to use mineral oil as a vehicle for any remedy to be injected into subcutaneous tissue. This fact has been well established in regard to paraffin injections, and the tumors resulting from the injection of camphor oil incorporated in a mineral oil strengthens the conclusion.

Oxycephaly.—This paper was abstracted in THE JOURNAL, Jan. 17, 1920, p. 201.

Surgical Treatment of Cysts of Thyroglossal Tract.—In 86,000 consecutive patients examined in the Mayo Clinic, only thirty-one cases of thyroglossal cysts were found. Eighteen of these were in males and thirteen in females. The cysts appeared at all ages from birth to 53 years, the majority being noted in patients between the ages of 20 and 25 years. In twenty-five of these patients the cyst was found in the midline of the neck, near the hyoid bone.

Stone in Kidney.—This paper was abstracted in THE JOURNAL, Jan. 17, 1920, p. 200.

Results of Operations for Removal of Stones from Ureter.—This paper was abstracted in THE JOURNAL, Jan. 17, 1920, p. 200.

Tuberculosis of Appendix.—Of 210 appendixes, only two, or approximately 1 per cent., were found tuberculous. Warwick cites a case in which the tuberculous appendix was the first definite evidence of the probable existence of other tuberculous lesions. The necropsy showed clearly that the primary lesion had resided for some time in the apexes of the lungs. An acute exacerbation of these lesions followed ulceration of the intestines and invasion of the appendix.

No Surgical Appendicitis Without Organic Stricture.—Pitzman claims that attacks of acute suppurative appendicitis are brought on by complete closure of a preformed stricture. The inflammation, eventually gangrene, is due to the action of the bacteria normally present in the locked-up feces. The true chronic appendix also has a stricture, which, however, is patent during intervals between attacks.

Sarcoma of Prostate.—Herrick analyzes sixty-two cases recorded in the literature.

Abscess of Prostate.—Sixteen cases of abscess of the prostate are cited by Randall in support of his belief that any infection of a pus forming character is, ipso facto, of gonorrheal origin. Eight cases were clinically diagnosed as prostatic abscess, secondary to an active gonorrhea arthritis. In the second group of eight cases, gonorrhea played no antecedent rôle. In two cases *B. coli* was the infecting organism, and in a similar number *Staphylococcus pyogenes-aureus*.

Development of Modern Infant Feeding: Influence on Present Teachings. L. W. Hill, Boston.—p. 311.
Anesthesia in Obstetrics. P. Appleton, Providence, R. I.—p. 321.

Tumor of Sacrum.—In the case cited by Goldthwait, a hard mass covered the whole anterior part of the sacrum and projected from an inch to an inch and one half into the pelvis. The swelling over the posterior part of the sacrum was not hard and did not obscure the general bony landmarks. The roentgen ray showed up the destruction of a large part of the central portion of the sacrum. In the light of the history of an evidently long continued condition with extremely good general function, it being possible for the patient to walk about with apparent ease, it was considered inadvisable to operate, and a support for the pelvis was planned to relieve the joints of the pelvis from the strain, and planned also to correct the unnatural forward inclination of the pelvis. This support was applied. The patient has been able all of the time to carry on a drug store business. She tired more easily than would be normal, but with two or three short periods of rest in the course of a day, together with a belt to give reasonable support about the pelvis and low back, it has been possible for her to keep about with apparently no increase of the difficulty and, on the whole, increasing general strength.

*Effect of Arteriovenous Fistula on Heart and Blood-Vessels. An Experimental and Clinical Study. M. R. Reid, Baltimore.—p. 43.
Biological Classification of Influenza Bacilli. T. M. Rivers, Baltimore.—p. 50.

Experimental Pneumectomy.—In twenty-three dogs on which total pneumectomy was practiced by Heuer and Dunn, there were thirteen recoveries and ten deaths. The fatalities occurred in from four days to two months after operation. Six of the deaths were due to an epidemic of distemper which swept through the kennels. The necropsy examinations in this group did not show a single instance of infection of the parietal wound or pleura or leakage from the bronchial stump. One animal died of a simple pneumonia unassociated with other evidences of distemper. At the necropsy there was no infection of the parietal wound or pleura or leakage from the bronchial stump. One animal died apparently from starvation, two months after operation. At the necropsy there was a remarkable degree of emaciation, but no other assignable cause for death. There was no infection of the parietal wound or pleura or any leakage from the bronchial stump. In one of these the failure to secure an adequate closure of the bronchial stump was intentional. In the other a necrosis of the bronchial wall followed the application of an intentionally flattened (not rolled) metal band.

Effect of Arteriovenous Fistula on Heart and Blood Vessels.—A report of experimental work on dogs is made by Reid, and fourteen clinical cases of arteriovenous fistula are reported in abstract. A study of the clinical cases reveals that the artery was observed to be dilated proximal to the fistula in five instances. In seven of the cases the histories do not comment on the size of the artery. In one case in which the fistula had been present for only three months, the artery was not dilated. In patients in whose history no mention is made of the size of the artery, the arteriovenous fistula was intracranial in three, in the hand in two, between the occipital vessels in one, and in femoral region in one. All the femoral arteriovenous fistulas, except two of three and four months' duration resulted in a proximal dilatation of the artery. This dilatation may extend as far as the heart. Marked cardiac disturbances may result from an acquired arteriovenous fistula of long standing. They are hypertrophy and dilatation with eventual cardiac decompensation. The wall of the vein involved in an arteriovenous fistula becomes hypertrophied. Although the vein on the proximal side of the fistula does not increase markedly in size, its wall shows a greater increase of elastic tissue than the wall of the vein distal to the fistula. The venous blood pressure is increased in the part of the body distal to an arteriovenous fistula. When the fistula is cured the pressure returns to normal.

Trichomonas Vaginalis Vaginitis.—De Lee states that in cases of this type the patient complains of obstinate vaginal discharge, pruritus, sleeplessness, burning, general weakness and of being "run down." The vulva is reddened, the vagina also, and often rough like a nutmeg grater; sometimes there are minute hemorrhages in the vaginal epithelium. The cervix is sometimes affected. The discharge is profuse, excessive, mucopurulent, thin, bubbly, acrid and with a disagreeable odor. Its irritating character is shown by the erosion of the skin, and especially in fat women there is an obstinate foul smelling intertrigo. Sometimes there are pointed condylomas. Diagnosis is easy. The clinical appearance of the vagina will suffice, but examination of the fresh discharge under the microscope will confirm it. As for the treatment: On the morning of the first day the vagina and vulva are scrubbed vigorously with tincture of green soap and water, using a rough cloth and going most thoroughly into every fold and crevice. The soap is then rinsed out with sterile distilled water. The process is repeated three times, then a 1:1,500 mercuric chlorid douche is given also with friction, every fold and crevice being washed. This again is washed out with sterile distilled water. The patient rests in bed. Next morning the vagina is again washed out with green soap and sterile water. Then it is packed with cotton soaked with glycerin (4 ounces) and sodium bicarbonate (1 ounce). The folds and crevices of the vagina are filled with the cotton and the vulva is smeared with the mixture. Next morning the tampon is removed and a sterile water douche is given. The following morning the secretion is examined under the microscope for trichomonads. Usually they are gone.

Nutritive Value of Proteins of Barley, Oat, Rye and Wheat Kernels.—The growth of rats on diets essentially comparable, except in respect to content and source of the cereal proteins contained therein, show the possibilities of nutrition when any one of the four commonly used cereal grains furnished the protein.

Determination of Chlorids in Whole Blood.—A modified technic for whole or laked blood is described by Austin and Van Slyke in which the precipitation and removal of the protein precede the addition of the silver.

Utilization of Calcium of Carrots by Man.—Two series of experiments to determine the utilization of the calcium of carrots by the human body were carried out by Rose on four healthy young women. The calcium intake was in every case close to the estimated minimum for equilibrium. In all cases but one there was a positive calcium balance on the carrot diet, and in this case the loss was small. When approximately 55 per cent. of the calcium was derived from carrots, one subject had practically the same retention as on a diet in which 70 per cent. of the calcium was derived from milk. It seems possible, therefore, to meet the requirement of the adult human organism for calcium largely, if not wholly, from carrots.

Effects of Feeding Calcium Salts.—The result of a study of the effect of the administration of calcium salts by mouth to men, cats and rabbits, made by Denis and Minot, indicates that in most cases it is impossible to increase the concentration of calcium in the plasma by ingestion of calcium salts, but that in cats and rabbits, in which the initial concentration is low, it is sometimes possible to greatly increase the amount of calcium in plasma by feeding salts of this element.

Determination of Magnesium in Blood.—The procedure described by Denis consists of the removal of organic material contained in the filtrate from the calcium determination, the precipitation of magnesium as magnesium ammonium phosphate, and the nephelometric determination of the phosphate in this compound by the reagent of Pouget and Chouchak.

Simplified and Improved Method for Determination of Sugar in Blood.—Folin and Denis have replaced their regular phenol reagent by a reagent which reacts with cuprous copper, in acid solution, yet gives no color with phenols.

Nutritive Value of Commercial Corn Gluten Meal.—The authors found that commercial corn gluten meal, supplemented by dried brewers' yeast, whole ground yellow corn, or coconut press cake, furnishes the necessary protein for normal growth. Eighteen per cent. of whole, ground, yellow corn meal furnishes sufficient water-soluble vitamin for normal growth.

Equilibrium Between Oxygen and Carbonic Acid in Blood.—Henderson endeavors to explain the interaction between oxygen and carbonic acid in blood by means of the theory of acid base equilibrium.

Pneumococcal Value of Whole Fresh Blood.—It is maintained by Bull and Bartual that the whole uncoagulated blood of immune animals is not as highly pneumococcal in vitro, as has been claimed. Cultures of pneumococci in the fresh whole blood of immune animals, as compared with cultures in the blood of susceptible animals, show a greatly prolonged latent period, and, in a general way, the relative lengths of the latent periods of the cultures correspond to the relative resistances of the animals to infection by these organisms. The blood of animals artificially immunized, both actively and passively, retards the growth of pneumococci in the same manner as the blood of naturally immune animals. The retardation of multiplication depends on two factors, opsonization of the pneumococci by the immune serum, and phagocytosis of the organisms by the polynuclear cells; growth readily occurs when either agent is absent.

Pneumococci multiply in defibrinated immune blood because few phagocytes are present after defibrination. Pneumococci grow in the most potent immune blood after mechanical destruction of the white cells. It was not determined that immune blood does not kill a certain number of the pneumococci with which it is inoculated, but the tentative conclusion has been arrived at that no killing occurs since none of the bloods tested became sterile during the course of the experiments.

Production of Specific Antiserums for Infections of Unknown Cause.—Rous and his associates state that there is present in serum of high precipitin titer, produced by the repeated injection of rabbits with a blood-free serum of guinea-pigs or dogs, a principle, highly toxic for animals of the species furnishing the antigen. Intravenously, the serum causes severe shock, and even sudden death, while locally, it gives rise to acute inflammatory changes and profuse capillary hemorrhages. The complete removal of hemolysins and hemagglutinins from the serum by exposing it repeatedly to washed red cells lessens its toxicity to only a slight degree and one obviously dependent on these elements; while the further removal of precipitin by specific precipitation *in vitro* has no detoxifying effect whatever. Whether the toxic principle is a hitherto unrecognized antibody or perhaps a toxic product of the interaction of precipitin and precipitinogen—one formed as readily in the test tube as in the animal body—remains to be determined. The symptoms of guinea-pigs and dogs given an intravenous injection of treated or untreated serum markedly resemble those of anaphylaxis, but attempts at desensitization were unsuccessful. The local lesion in guinea-pigs is more severe than that of the Arthus phenomenon.

Deterioration of Crystalline Strophanthin in Aqueous Solution.—Experiments were undertaken by Levy and Cullen to ascertain the cause of the deterioration of aqueous solutions of strophanthin in relation to the altered hydrogen ion concentration, and to devise a method for preparing a stable solution for therapeutic purposes. Many of the glass containers commonly used in the laboratory, and most of the glass ampoules employed in marketing sterile solutions for hypodermic or intravenous medication, were found to yield sufficient alkali on autoclaving, to change the reaction of distilled water from pH 6.0 to pH 9.0. This increase in alkalinity is sufficient to render biologically inert and partially to decompose aqueous solutions of crystalline strophanthin in the concentration ordinarily employed in the clinic. It is suggested that for clinical use, crystalline strophanthin be dissolved in 0.02 M standard phosphate solution at pH 7.0, and marketed in hard glass ampoules, thereby insuring stability of reaction with preservation of biologic activity.

Iso-Agglutinins in Infants and Children.—The iso-agglutination of 131 infants and children from birth to 10½ years was examined by Happ by testing their serum and washed corpuscles microscopically against the serum and washed corpuscles of each of four adult groups. The grouping as present in adults is rarely present in blood from the umbilical cord. At birth and during the first month of life, isoagglutination is rarely present, but the percentage of infants in whom the iso-agglutinin group is established increases with age, so that after 1 year the group is usually established, and after 2 years it is always present as in adults. The grouping is established in the corpuscles before it is established in the serum; i. e., the corpuscles acquire agglutinophilic receptors before the serum acquires agglutinin. Therefore, Group I is the first group to be formed and Group IV is the last. The early grouping in the corpuscles before the group is established in the serum is liable to change by the acquisition of new receptors. When the grouping has been established in both serum and corpuscles it does not change. Iso-agglutinins are present in mother's milk and the grouping is identical with that in the mother's blood. These agglutinins are probably not transmitted to the nursing infant through the milk. On account of the difference between the agglutination reactions in the blood of mother and child, it is not safe to transfuse an infant from its mother without making the preliminary tests.

Effect of Feeding Pineal Body on Development.—Feeding the desiccated pineal body of young calves to young albino rats failed to produce any effect on the early development of these animals.

Treatment of Brain Abscess Following Middle Ear and Mastoid Infections.—A number of different procedures for the purpose of forming a safety zone through which to operate have been tried out by McKay but he has not yet reached definite conclusions.

Case of Temporosphenoïdal Abscess.—The case cited by Leshure is of interest chiefly from the standpoint of diagnosis. None of the classical symptoms of brain abscess were present, although a rather persistent headache should have aroused suspicion of deep-seated trouble. Incision of the right temporosphenoïdal lobe evacuated about 30 c.c. of very foul thick greenish pus mixed with cerebrospinal fluid. As the patient's heart had not ceased to beat, the incision was enlarged and digital exploration revealed the fact that the abscess was encapsulated but evidently was not of very recent origin. No stalk or direct communication with the middle-ear cavity could be made out.

Clinical Study of Ectopic Pregnancy.—Among 580 cases of gynecologic operations analyzed by Stein, there were forty-three cases of ectopic pregnancy, or 7 per cent. Only six of the forty-three women had never been pregnant. Thirteen were primiparas. Only six patients gave a history of previous miscarriage. Three patients had been operated on for a former extra-uterine pregnancy. A long period of sterility is usually regarded as an antecedent to an ectopic pregnancy. This fact is not borne out by Stein's study. One patient had been sterile thirteen years, and one eleven years, but the great majority had become impregnated within the last three years. In these forty-three cases, a double salpingectomy was deemed necessary only nine times. Thus the other tube showed evidence of inflammatory involvement in about one fourth of the cases. Of those tubes that were sectioned throughout, only about one third showed the presence of round cell infiltration and connective tissue replacement, due to chronic inflammatory

changes. It is Stein's opinion that the normal meeting place of the ovum and spermatozoon is in the uterus. Various factors may account for the meeting taking place in the tube: (1) late ovulation; (2) hypermotility of the spermatozoon; (3) lodgment of the ovum in a recess or congenital ampulla of the tube; (4) mild salpingitis.

Treatment of Syphilis.—After reviewing about 4,000 Wassermann tests, Trimble finds himself forced to the conclusion that primary syphilis is never cured. This belief is based on the observation of patients having had their infection a few years ago and having had modern intensive treatment. What may be the proper treatment for early syphilis Trimble finds it difficult to say. He is inclined to the view that one primary fault lies in the too universal acceptance of the specificity of certain drugs. Long periods of latency may, he thinks, be rightfully attributed to an acquired immunity and not wholly to the treatment received. The most unfortunate state in which a patient could be found is where he harbors treponemata and at the same time has nothing but arsphenamin or mercury to protect him. Trimble concludes his paper with the statement that syphilis cannot be cured, and that the best treatment is that which will give the patient the longest lease on life and usefulness to himself and society.

Is Psoriasis Incurable?—Among the internal medications those of first importance in Hammond's opinion seem to be: arsenic, iron, nux vomica, the potassium salts, vegetable tonics, iodids, mercury, suprarenal, thyroid and pituitary extracts and vaccines. As to diet, he aims to balance the diet by increasing the amount ingested of those foods which are the least harmful to the patient. Of external measures, Hammond favors the rays of the Alpine sun lamp, judiciously applied, and mild application of the roentgen ray can be used on the nonhairy surfaces, but, he says, as a rule, resorcin, in a lotion to the scalp, and a mild ointment of ammoniated mercury elsewhere, are all that will be required.

Case of Mixed Hypothyroidism and Hypopituitarism.—Eustis and DeBuys report the case of a girl, 15 years of age, who, two years ago, presented symptoms of hypothyroidism, while during the past two years she has developed well defined symptoms of hypopituitarism. She has the mental and physical development of a child of 5. Her most marked symptoms are: weakness, unsteady gait, obesity, dryness of the skin, lack of physical and mental development and wetting of the bed. Her coordination of muscular movements is so poor that she is unable to feed herself. Constipation has been a prominent symptom for six years. For one month she has had a capsule, three times daily, consisting of 2 grains of extract of the whole pituitary gland, 1 grain of extract of thyroid, and 1 grain of ovarian extract. The authors believe that the condition is one primarily of the disturbance of the anterior lobe of the pituitary gland in which there is a diminished secretion, with secondarily a diminished secretion of the thyroid.

Sponge-Forceps Method of Treating Incomplete Abortion.—No originality is claimed by King for the method he uses. The patient is always anesthetized, is carefully prepared with green soap and water, followed by alcohol, a self-retaining speculum is introduced, the cervix is grasped by a volsellum and dilated gently (if necessary). In the majority of cases, the cervix is open enough to admit the sponge forceps or the finger, and no dilation is necessary. Ordinary sponge forceps are introduced, and with them the retained secundines are seized and withdrawn. The forceps are introduced and withdrawn two or three times, until no more remnants are found, and then are introduced with a sponge in their grasp, which is twisted around inside the uterus to remove any small particles that may be left. Finally, if the cervix is sufficiently dilated, the finger is introduced and the cavity carefully palpated in order to make sure that all particles have been removed. This step is not regarded as essential, and is often omitted, as the cessation of bleeding is a very reliable indication that the cavity is empty. The uterus is not irrigated; no chemicals are used in its interior, and no pack is used, except in the rare case in which rather free bleeding persists in spite of complete evacuation. The after-treatment is simply rest, local and general, for from three to six days. The patient is allowed up as soon as the uterus has involuted well, and she is discharged two or three days later. King has found that this method is as effective as the use of the curet in the removal of the retained material, is not followed by fever, and is not attended by any risks.

Chronic Appendicitis.—In Stanton's experience chronic appendicitis has proved to be a rather sharply defined disease in which the symptoms may be recognized by the fact that they produce in miniature the first symptoms of the acute attack. The disease differs from the acute appendicitis by the fact that the obstruction is incomplete or because it is habitually relieved before the acute inflammatory stage develops. The pathologist's report, based on the microscopic examination of so-called chronic appendixes is unreliable. Most symptom producing chronic appendixes may be recognized at the operating table by the presence of gross anatomic factors predisposing the appendix to attacks of partial or complete obstruction of the lumen.

Heart in Focal Infections.—Greiwe suggests that chronic septicemia, due to pyorrhea alveolaris, must be given serious attention in considering the etiology of inflammations and degenerations, as well as dilations of the ascending aorta, the arch and the descending aorta.

Streptococcus Viridans Infections of Mouth and Throat with Reference to Neuritis and Arthritis.—In Hay's experience, *Streptococcus viridans* plays a very important rôle in the etiology of cases of neuritis and arthritis which are not accompanied with swelling and fever, a feature of differential diagnostic importance. Granted the elimination of the source of toxemia, an autogenous vaccine of the cultured *Streptococcus viridans* has given markedly beneficial results in Hay's cases.

Intravenous Protein Therapy.—Gow has given peptone intravenously in conjunction with sensitized vaccine subcutaneously in streptococcal septicemia, and is convinced of its value in such cases. In certain forms of arthritis great benefit has been derived from intravenous protein therapy. Here the vaccine is given entirely for a shock effect. The type of joint disease which responds best, in Gow's experience, is the multiple infective arthritis for which no active source of primary infection or septic absorption is demonstrable. While Gow regards intravenous protein therapy as of great value in certain carefully selected cases—more particularly of arthritis, the septicemias and coliform infections—he states most emphatically that it is not a panacea for all ills; and even in those diseases in which it is of use it is to be regarded solely as an accessory weapon in conjunction with, not to the displacement of, other remedies.

Poison of Spiny Dogfish.—A case of acute edema, the result of a prick by a dogfish, is reported by Evans. A fisherman sustained a punctured wound at the base of the thumb infected by a dogfish. The injury was followed by acute

stabbing pain in the part which lasted four or five hours; the hand then began to swell, and when the patient arrived at the hospital there was great swelling and edema of the back of the hand, and the front of the wrist and forearm were painful, tender, red and edematous. This acute inflammatory edema lasted for four days and for a time it seemed that suppuration would occur. On the fifth day the edema at the back of the hand had subsided, but it was not until seven days had elapsed that the tenderness and swelling over the wrist had disappeared and the patient was convalescent. The treatment adopted was to paint the hand and the front of the wrist and forearm with liniment and solution of iodine in equal parts and apply hot fomentations.

Metastatic Staphylococcal Infection of Kidney.—The infection of the kidney observed by Souper followed on operative interference with an infected wound of the forearm. The condition cleared up on treatment with an autogenous vaccine.

Volvulus of Cecum: Double Obstruction.—The original lesion in the case cited by Smith was a tuberculous affection of the mesenteric glands leading to a strong adhesion between the hepatic flexure and the last 2 inches of the ileum. The early stages of this were noted in the atypical gastric symptoms due to an ileac "kink" and obstruction to the ileac efflux, so often mentioned in the literature. Some indiscretion of diet, followed by decomposition of the contents of the cecum produced a "balloon" of this viscus, which, being mobile, rose up, turned on a hinge and become a volvulus, producing further obstruction at the already kinked hepatic flexure. Relief of this obstruction and the replacing of the cecum away from the ileum brought into force a second kink in the ileum from which ensued the intestinal obstruction.

Prophylactic Inoculation with Influenza Vaccine.—The results obtained by Yabe in two series of experiments seem not to favor the possible protection of the animal by the administration of the vaccine. If the results of the experimental active immunization of the animals against influenza and of the passive immunization of the animals (with the convalescent serum) are considered antithetically, they both do not appear to produce a complete protection. It is, however, an interesting fact to note that the convalescent serum contains a certain amount of immune bodies, although in a very small quantity. This may be taken as the standard for the possibility of the production of protective properties in the vaccinated.

*Acute Total Inversion of Parturient Uterus. H. T. Whiting and N. Glover.—p. 495.

Influenza as Etiologic Factor in Nephritis.—The points emphasized by Thompson and McCauley are: Nephritis is a more frequent complication of influenza than is commonly thought. The virus of influenza may affect the kidneys in various ways: (a) By producing a temporary albuminuria as seen in many other acute infectious fevers. (b) By causing an acute nephritis during the course of the disease, especially if respiratory symptoms are present. (c) Nephritis may arise during convalescence, as in scarlatina. The damage of the kidney may not become manifest until the patient is believed to have recovered from the original disease. (d) A dormant or latent nephritis may be lighted up. Nephritis may follow even mild cases of influenza. Nephritis occurring during the course of influenza may be masked by the respiratory symptoms and only careful routine examination of the urine may demonstrate its presence, while some of the cases arising after the symptoms of influenza have abated may show such slight symptoms—transient edema, slight oliguria, or capricious albuminuria—that they may easily be missed. The authors report four cases occurring in one family. In all these cases a careful inquiry was made as to the possibility of renal trouble existing previous to the influenzal attack, but the suspicion was absolutely discounted in every case.

Factors Concerned in Asthma and Their Treatment.—In the treatment of asthma, Jones maintains one has to consider an irritable center, hysterical influence of that center, infections of the bronchi and parts of the lungs below them, more especially with specific bacteria whose toxins induce the paroxysms, abnormalities of the respiratory tract superior to the bronchi, and irritation of viscera outside the respiratory tract altogether. For the center the use of sedatives, and the usual psychical methods applicable to hysteria must be employed as required. For the nose and throat, surgical methods are generally needed, and appropriate treatment must be given to other visceral disturbances. As to the respiratory tract proper, bronchitis must be treated in some way or other. It is a bacterial infection, and in all recovery from such infections the natural capacity of the body to elaborate antibodies is required for which the only therapeutic measure is treatment by appropriate vaccines; finally, if the hypothesis as to the specific character of certain bacterial toxins in the causation of asthma is correct, that cause also can frequently be combated by the employment of vaccines. It is submitted that this constitutes a scheme for the treatment of the asthmatic state on rational lines.

Pancreatic Insufficiency.—The case reported by Symes is said to lend support to the view that oxaluria may arise from the fermentation of carborydrates in the digestive tract. In this instance the faulty digestion of starch was due to the insufficiency of the pancreatic secretion. The first attack of oxaluria occurred thirty years before the patient's death, and the author believes that probably at this time there was commencing fibrosis of the pancreas. Seventeen years later oxaluria recurred, and with it glycosuria and albuminuria. The glycosuria was never severe, and six years later, when the patient was carefully dieted, it disappeared, to return only on one or two occasions, when he had broken his dietary régime. It was an alimentary glycosuria, and to the end of his life the patient preserved sufficient pancreatic substance to prevent the appearance of the signs and symptoms of diabetes. A stone in the pancreatic duct gave rise to an acute attack during the autumn of 1911. Apparently it ulcerated its way out of the duct into the bowel. The characteristic stools of pancreatic insufficiency were noted some months before there were symptoms of a stone in the duct. The fact that the symptoms and signs became more pronounced after the stone had disappeared, Symes says, was owing, no doubt, to cicatrization and gradual narrowing of the lumen of the duct and the ever-increasing fibrosis of the pancreas. Other points of interest in the case are: (1) The

rapid and ultimately fatal rise of blood pressure due to auto-intoxication from the bowel or to imperfectly antagonized suprarenal secretion. (2) The long continued good nutrition and physical and mental energy shown by the patient, which indicates to how great an extent pancreatic digestion may be assisted by other organs. (3) The relief afforded to the patient by withdrawing fat from the diet and giving acid preparations by the mouth (acidol pepsin, betain chlorid) after meals, the increased acidity stimulating the flow of secretion, and thus increasing both the internal and external secretions of the pancreas.

Resection of Impassable Stricture of Urethra.—The method of treatment described by Harris is founded on the following basic principles: (1) that the perineal portion of the male urethra may be slit up on its floor to any desired extent and thus converted into a "ribbon"; (2) that any damaged portion may then be resected and the ends of the "ribbon" sutured together; (3) that, finally, provided no urinary contamination of the wound be permitted, the urethra will resume its tubular form naturally and in due course.

Value of von Pirquet's Test for Tuberculosis in Children.—Observation has confirmed Litchfield's belief that the von Pirquet test for tuberculosis in children, when used and interpreted with discretion, is of considerable clinical value.

- *Signs of Insufficiency of the Stomach. M. Labbé.—p. 321.
*Symptoms of Dysentery with Uterus Disease. M. Devic and M. L. Bouchut.—p. 346.
*The Stomach Disturbances After Vaccination Against Typhoid. L. Timbal.—p. 351.

Signs of Insufficiency of the Stomach.—Labbé comments on the close physiologic and pathologic connection between the stomach, intestine, pancreas and liver, so that it may be impossible to tell which organ was the primary one involved, but study of the gastric secretion may give the clue to the whole clinical picture. He prefers Töpfer's dimethylamido-azobenzol colorimetric method, as modified by Linossier, as the simplest and most rapid technic. Repeated examination revealing constantly abnormal findings indicates ulcer or persisting dyspepsia. The main point, he reiterates, is to regard the digestive apparatus as a whole and not center our investigations on any one organ alone. Even with hyperchlorhydria, this may not be responsible for all the symptoms, and there may be violent pains in the stomach with hypochlorhydria, showing that spasm of the pylorus is the cause of the pains, even with hyperchlorhydria. In his group of cases of hyperchlorhydria there were four of typical and six of probable gastric ulcer, and others with chronic enteritis, gastro-intestinal atony and dyspepsia of indefinite types. The hypochlorhydria group included cases of enterocolitis, gastric atony, gallstones, insufficiency of the liver, neuropathies, and in one case a gastric ulcer. In the group with

anachlorhydria, more than half of the patients had enteritis, and others insufficiency of the liver, neuropathies, gastralgia and anemia, alcoholic gastritis or ulcerative perigastritis.

Dysentery with Uterus Disease.—Devic and Bouchut report two cases in which symptoms suggested dysentery but resisted all treatment on this basis. They subsided at once in one case after discovery of a small fibroma on the rear wall of the uterus, pushing in the rectum wall at this point, and the uterus was removed. In the second case simple retroversion of the uterus, pressing on the rectum, caused the symptoms supposed to indicate dysentery. In the first case the symptoms were of long standing, and the condition was so grave that the woman did not long survive. In the retroversion case the supposed dysentery was of only two months' duration. The patients were 50 and 43 years old. The entire pelvis should be examined with intestinal disturbance.

Stomach Disturbance After Vaccination Against Typhoid.—Timbal reports a personal case and cites three others from the records in which hematemesis followed the vaccination. They teach the importance of investigating the history, and refraining from vaccination on suspicion of ulcer or cancer. Simple dyspepsia is not a contraindication.

*Radium Treatment of Cancer of Cervix. Recasens (Madrid).—p. 676.
*Bactericidal Action of Radium. P. Lequeux and E. Chomé.—p. 698.

Radium Treatment of Cancer of Uterine Cervix.—Recasens has been treating malignant disease of the cervix with radium since 1913, and many cases of supposedly inoperable cancer have been cured for three, four and five years to date. He is seeking with so many others to learn why it failed in 30 or 40 per cent. of his over 400 cases, even when conditions, structure, etc., seemed identical. Another astonishing feature of radium treatment is that sometimes when it seemed to have failed completely and the treatment was abandoned as hopeless, the woman returned months later immeasurably improved or even clinically cured. There had evidently been a cumulative action from the radium, and the organism had rallied some mysterious forces to its support. These mysterious forces must be discovered and harnessed in our service. The cancer and the radium both depress the numbers of leukocytes, and we must seek to induce leukocytosis as an aid in the fight against the malignant disease. His experience confirms further that the toxic cachexia is aggravated by radium treatment which pours more toxins into the circulation. Before the radium is applied, the number of leukocytes must be increased and the best means for this, he says, is by application of diathermy to the spleen. Almost at once the blood usually shows increased numbers of leukocytes. It has long been known, he says, that the spleen has a cancerolytic action, but no means has been devised as yet that will enhance this.

No drugs were found effectual except that colloidal copper by the vein seemed sometimes to augment the susceptibility of the cancer cells to the radium, the cure being realized earlier in these than in other cases. This encourages further search for chemicals which may alone cure cancer, but for the present we can use it as an adjuvant. Numbers of chemicals were tested locally, and also diathermy but none displayed any efficacy. To avoid secondary infections, he treats the cancer with a 10 per cent. solution of copper sulphate before applying the radium and douches the vagina with a 1 per cent. solution. The amount of radium used is 70 mg., at eight day intervals, and the glands in the region are given supplementary roentgen treatment. The papillary form of cancer is most amenable to radium when the tube can be placed so it is completely surrounded by the excrescences of the tumor.

Action of Radium on Bacteria.—Lequeux and Chomé were unable to detect any destructive influence from the radium rays on the typhoid and colon group. The rays arrest the progress of the culture, check production of pigment, and cause agglutination, but no bactericidal action was evident except for the gonococcus, and perhaps also for the streptococcus. The action of radium on bacteria in the blood stream

was not demonstrated, but certain facts observed are certainly significant, namely, that one mouse thus treated survived experimental pneumococcemia; rabbits developed milder sepsis after inoculation with staphylococci, and a few other similar experiences.

*Therapeutic Anti-Anaphylaxis. J. Danysz.—p. 155.
Treatment of Vomiting in Children. Stévenin.—p. 157.

Therapeutic Antianaphylaxis.—Danysz' method of treating disease by combating the factor of anaphylaxis has already been described in these columns, June 7, 1919, p. 1707. He here describes anew the technic and his experience in 352 cases since 1913. In seeking for an efficient antianaphylactic, he started from the theory that the focus for production of the substances generating the anaphylaxis in the majority, if not in all, of the chronic, noncontagious diseases, is in the bowel: The albuminoid matters or microbial contents of the intestinal canal passing into the blood through the congested intestinal mucosa act as antigens and induce the anaphylactic state of the organism. Consequently, he reasoned, the microbes isolated from the intestinal contents ought to act as antigens when inoculated or ingested. The microbes are isolated from a scrap of stool by sowing on ordinary culture bouillon and then making pure cultures on gelose, and then mixing the cultures in the same proportions as found originally. This is diluted with physiologic serum, sterilized with heat and the dose determined by weight. For ingestion, the dose is $\frac{1}{10}$ to $\frac{1}{20}$ mg. of the microbial bodies; for injection $\frac{1}{1,000}$ or $\frac{1}{1,200}$ mg. At first he made an autogenous antigen for each patient, but finding that the species and proportions of bacteria were so uniform, he used a polyvalent heterogenous preparation in some cases. The results were less pronounced when a single species was used. In treating the tuberculous, he added a little tuberculin to the polyvalent entero-antigen, as he calls the preparation. The treatment is based on the same principle as the protein therapy, peptone injections, parenteral milk injections, etc. "It is almost absolutely harmless," he says, "and its action seems to be not directly on the lesions of the disease but on the central nervous system, and especially on the medulla oblongata. This in turn reacts with a stimulating or regulating effect on the glandular functions, just as we find an attack of fatal anaphylaxis can be aborted by a strong dose of alcohol or ether taken before the dose that induces the anaphylactic attack. We know also that a more or less generalized anaphylactic attack can be brought on by intense fear or grief. All this shows that the central nervous system can be deadened or whipped up enough to prevent or induce these cellular metabolisms which are revealed by the symptoms. . . . We know also that the cell reactions which have as their immediate definite results a diarrhea, attack of asthma or urticaria, are always of the same nature, whatever the primary cause of the crisis; whether it is an emotion, an odor, a sensation of cold or an antigen. We thus have reason to assume that in the nonspecific reactions it is always some reaction in the central nervous system which starts the crisis or aborts it or cures it. . . . The evidence to date indicates that the antigens derived from the stools are the most potent yet known for influencing the nerve centers in this way."

The dose of the entero-antigen must be very small to begin with (0.05 or 0.1 c.c. of a dilution containing 0.01 mg. of microbial bodies per 1 c.c.). It is best to avoid a febrile or other reaction (except in psoriasis). The 352 cases treated include many of urticaria and eczema cured for over four years without recurrence; of psoriasis and epilepsy cured for over a year; of asthma and emphysema for more than three years; and of glandular, renal and testicular tuberculosis cured for over two years. But in some of the cases of psoriasis,

dysmenorrhea or gastro-intestinal disease there was recurrence in three or six months, but these yielded promptly to resumption of the entero-antigen. In nervous disturbances the effect is usually apparent at once, but in constipation it may not become apparent until several weeks after a series of eight or ten injections. Cures have been realized in 90 per cent. of all the cases treated, with the exception of psoriasis, in which only 60 per cent. were cured, and in epilepsy. Complete and durable remissions were realized in epilepsy only in children, although the seizures in adults were mitigated and rendered less frequent. In addition to the pathologic conditions already mentioned, his list includes arthritis, rheumatism, slight chronic albuminuria, and the disturbances of the menopause.

- Mesenteric Thrombophlebitis with Latent Cirrhosis. A. Cade and P. Brette.—p. 114.
- Facial Paralysis in Influenza. A. Porot and N. Sengès.—p. 118.

Treatment of Diphtheria.—Weill-Hallé obtained superior results, he says, when he gave the antitoxin in a single large intramuscular dose. As a rule he makes the injection in the buttocks, injecting 250 units in moderate cases per kilogram of weight, and from 500 or 600 units in the graver cases. It is seldom necessary to supplement this with subcutaneous injections.

Fibrous Rheumatism.—Lereboullet and Mouzon illustrate the extreme dislocation of the fingers in the case described, evidently merely from relaxation of the ligaments and capsules of the joints involved.

Myoclonic Acute Encephalitis.—Sicard and Kudelski report four cases of a disease commencing with severe neuralgias, lancinating pains, general depression, and moderate fever; then comes a period of brief rapid rhythmic myoclonus, explosive twitching of the muscles in various segments of the body. The neuralgias persist and the third week there is delirium, while the myoclonic play of the muscles becomes attenuated; the diaphragm may keep up the myoclonus to the last. All but one of these cases passed into fatal coma. Netter stated in the discussion that followed that he had encountered some cases of this myoclonic type associated with lethargic encephalitis, and some cases of the latter which began with severe neuralgias. He said further that in 1918 the appearance of lethargic encephalitis preceded that of influenza. He thinks that probably the factors responsible for influenza are the same ones which entail the other disease, although the two diseases are separate entities.

Meningeal States with Narcolepsy.—Claude reports three cases recently observed which seemed to represent a condition midway between actual meningitis and lethargic encephalitis. They ran a rapid course, with recovery. They differed from epidemic and tuberculous meningitis by the prolonged torpor and somnolency, diplopia and ptosis.

Friedländer Bacillus Pleuropneumonia.—The woman of 40 developed septicemia, the work of the Friedländer bacillus, starting in a fetid rhinitis and localizing in a lobe of one lung and also in the biliary apparatus, inducing jaundice, with final recovery in a month although an old heart disease had rendered the outlook dubious at first.

- Technic for Bacteriologic Control of Cure of Urethritis. E. Roucayrol and Renaud-Badet.—p. 469.

Hypospadias.—Nové-Josserand has reconstructed the urethra in thirty-five cases of hypospadias and five of epispadias with full success in thirty-seven instances. The tube drawn into the tunnel was made of skin, the epidermis inside, and it was drawn over the segment of the normal urethra, through an incision 6 or 8 cm. long, exposing the urethra from below. The first step is to divert the urine by a hypogastric cystostomy. He advises to operate as soon as possible after birth to allow the corpus cavernosum to develop properly. The long incision, including the hypospadias meatus at about the center, is sutured with No. 00 aluminum bronze wire over Galli tubes placed on each side of the incision to bring the lips largely into contact and ward off all danger of a fistula. The wires are passed through the base of the skin flaps, about 1 cm. apart, leaving a minute opening at the proximal end of the incision for drainage. The details of the operation are shown in seven illustrations and the technic commended as an improvement over others in vogue.

Absence of Ejaculatory Duct.—Ancel found that this duct was missing in four specimens recently examined. The anatomic conditions responsible for this differed widely.

Calculi in Both Kidneys in Girl of Five.—Moran had to operate on both kidneys at the same sitting to remove the multiple calculi responsible for the anuria. The child has developed normally but the urine is still turbid four years later and contains formed elements and bacteria.

- *Solar Plexus Sign with Abdominal Neuropathies. Fraikin.—p. 143.
- Organic Hemiplegia in the Gassed; Two Cases. E. Terrien.—p. 145.

Cardiac Influenza.—Minet and Legrand comment on the scarcity of communications dealing with the heart complications of influenza. They have encountered six cases. They discuss in connection with these cases the various sets of symptoms that may be presented according as different parts of the heart, the innervation or the endocrine glands are affected. The prognosis is always grave for the organic forms, and should be reserved for all types, especially with an already fatigued or damaged heart. Absolute repose is indispensable, with revulsion or ice to the region, and stimulants for the heart, as needed, and suprarenal treatment, which may have an actually causal action.

Parchment Dermatitis.—Gougerot describes a streptococcus-staphylococcus dermo-epidermitis in which the skin peels off in large thick scales, like the bark of a tree. It proved in his six cases to be the most tenacious of these microbial dermo-epidermitis types.

The Solar Plexus Sign in Abdominal Neuropathies.—Fraikin says that when the nervous apparatus of the abdomen is out of order, there may be spontaneous pain or tenderness in the solar plexus. It is a sign that the circulation is hampered in or outside of the viscera, or the nerves are suffering from toxic action or from traction from sagging organs. This solar sign may serve to differentiate a purely nervous affection from an organic visceral lesion and it may guide to proper treatment of the neuromotor dyspepsia, general neuropathies, etc. Physical agents are generally the ones indicated.

Presse Médicale, Paris

- *Anaphylaxis to Acetylsalicylic Acid. F. Widal and P. Valléry-Radot.—p. 93.
- *Malaria with Subnormal Temperatures. R. A. Gutmann and R. Porak.—p. 95.

Anaphylaxis to Acetylsalicylic Acid.—Widal and Valléry-Radot report a case of actual anaphylaxis to acetylsalicylic acid, persisting for nine years. Then a systematic effort was made to overcome this anaphylaxis by giving the drug twice at an hour interval, first 0.005 gm. and then 0.25 or 0.5 gm. This was repeated thirteen times in six weeks—the preliminary doses increased from 0.005 to 0.03 gm.—and this sufficed to cure completely all tendency to the anaphylaxis.

It was of the typical alimentary type, and the desensitization was realized with the technic effectual in this type. They remark in conclusion that clinical observation rarely allows us to watch the modifications insidiously going on in the organism. But once in a while we encounter conditions which, as in this case, enable us to trace the series of these transformations with the precision of experimental research. When such an occasion arises, we should seize and record it with scrupulous care as it may by comparison reveal the significance of certain pathologic phenomena hitherto inexplicable. By compiling data, as in the case here reported, we may discover the origin of a whole series of pathologic conditions the cause of which can be traced to some preceding sensitization, which might be cured by desensitization.

Hypothermic Malaria.—Gutmann and Porak give some charts from cases of malaria in which the disease progressed by regularly intermittent phases in which the temperature dropped below normal instead of soaring above it. This hypothermic form entails cachexia or grave complications the same as the ordinary form, unless arrested by treatment in time, but on account of the absence of fever the malaria may be misinterpreted.

 Allowing Parturients to Get Up Early. J. Audebert.—p. 421.
 *Bilateral Ovariectomy During Pregnancy. A. Grosse.—p. 424.

Guinea-Pigs and the Gonococcus.—A predisposition has to be induced before guinea-pigs can be used for experimental research with the gonococcus. Besse and Christidès think that this could be accomplished by modifying the diet, but the three animals tested did not yield conclusive results.

Bilateral Ovariectomy in the Pregnant.—Grosse adds another case to the fifty-two cases he has found on record in which both ovaries were removed during the first four months of pregnancy. The operation is no more dangerous on the pregnant than on other women. The pregnancy continued unmoled in all except in 13.7 per cent. This testifies that the corpus luteum is not indispensable for the development of the fetus. With unilateral ovariectomy, the abortion followed only in 11.5 per cent. in the first three months, and in 3 per cent. in the fourth month, in a recent compilation, while with bilateral ovariectomy the proportions were 25 per cent. the first two months, 11 the third, and 12 the fourth. In Grosse's own compilation, the figures were 16, 11.75 and 10 per cent. in these months. These figures suggest a possible influence exerted by the corpus luteum on the pregnancy, and warn that it is better not to remove the ovaries early during a pregnancy except for urgent indications. Three pages of bibliography on the subject are critically reviewed.

 Lymphosarcoma of the Spleen. G. G. Moppert.—p. 40.

Evolution of Medical Organization.—Exchaquet concludes his study of this subject by urging that medical students should be taught the ethics of the profession, and that the leaders of the profession should take special pains to counsel and guide young physicians in the right path. The medical faculty at Lausanne have announced a lecture on deontology in each semester, and the professors are instructed to draw the attention of the students to such matters, and inculcate the principles of medical ethics.

Diagnosis of Mastoiditis.—Local pain and high fever, in children, and deafness usually warn that the otitis has spread to the mastoid when they persist longer than two or three days after ample drainage of the ear and other proper measures. If the fever is of the pyemic type, an operation should be done at once, even if the mastoid is not tender. If signs

of meningism do not subside by twenty-four hours after perforation of the tympanic membrane, the operation should follow at once, as also in case of vertigo and spontaneous nystagmus. Even without other signs, if the suppuration keeps up profuse for a month, the mastoid is probably involved. Terrier adds that cholesteatoma is a great purveyor of intracranial complications. Even in syphilis an operation is required, supplemented by specific treatment. Mastoiditis of mechanical nasal origin is not rare, secretions being forced into the eustachian tube by sneezing or blowing the nose; he has had seven such cases in the last few months, in which the infection spread directly to the mastoid. The severe complications in these cases confirm the necessity for operating immediately in mastoiditis of nasal origin, even if the temperature is normal. In any event, operate when there is suspicion of mastoiditis without waiting for absolute certainty. Diabetes entails a special predisposition to necrotic processes in bones; and mastoiditis is liable to be exceptionally grave in influenza, scarlet fever, diphtheria, measles and typhoid. The destruction in the first two proceeds unusually rapidly, but the recent epidemic of influenza usually spared the ear.

 Technic for Raying after Removal of Cancers. H. Hopf and I. Iten.—p. 91.

Treatment of Bending in of the Ankle.—A wedge-shaped insole straightens the foot and cures the deformity in time, but it has to be carefully graded to the exact degree of deformity. To measure this, Iselin has the man stand the foot on two superposed blocks of wood, the inner edges of which can be jacked up to the height required to bring the median axis of the foot and leg into a vertical line, determined by line and plummet. The wedge insole is then made to correspond to the slope of the upper block on the lower, as shown in the illustrations. In this connection Iselin discusses the Swiss army shoe and points out certain remediable defects in this and in civilian shoes.

Measurement of Goiters.—Hunziker measures the width of the thyroid and the height of the side lobes, in centimeters. Multiplying the two figures gives the area of a square in which the thyroid can be imagined to fit as an ellipsoid figure. The area of this square allows an estimate of the size of the thyroid in different persons and at different times in the same person. We thus have a reliable and easily ascertained measure for the thyroid so that goiters in different lands and at different periods can be compared. When the gland cannot be palpated, the record is 0; with 1:1, the record would be 1; with measurements of 6:5 cm. the record would be 30; with measurements of 17:12 cm. the record would be 204, and so on. He urges that this standard scale be adopted and large series of records obtained in different countries so that the actual prevalence of goiter and its size in a given region, its maximum at a certain age and certain year or season, and other questions can be determined on an international scale.

*Lethargic Encephalitis: Symptoms and Course. G. Sabatini.—p. 97.
*Idem: Bacteriology. G. Gabri.—p. 106.
Idem: Four Cases. C. F. Oggero.—p. 109.
Idem: On East Shore of Adriatic. L. Pergher.—p. 111.
Idem: History. L. and P. Fornara.—p. 113.

Lethargic Encephalitis.—Besides the five comprehensive articles listed above, the society transactions report a large number of cases of lethargic encephalitis at Bologna, Parma, Modena and Ancona. Sabatini mentions a case in which a man left Verona, where the disease was epidemic, and went to Calabria where the disease had not appeared at the time. Twenty days after his arrival he developed a typical case, which suggests that the incubation is about three weeks at least. The disease appeared in Italy last winter, but did not assume an epidemic character until this winter. He has had twenty-nine cases in his service at Rome. The lack of symptoms common to other diseases liable to be confused with it, is the most reliable diagnostic sign. One of the earliest symptoms was a rhythmic twitching of muscles, especially of the rectus and transverse abdominal muscles, and in the arms, neck and face, similar to the jerking induced by an electric stimulus. The rhythm of this twitching of the abdominal muscles was about 40 per minute in one case. Roentgenoscopy showed that the diaphragm did not participate in the movement, and that it was independent of the respiration rate. Chilling accentuated it and it kept up during sleep, and morphin did not suspend it. This sign sometimes gave the clue to the clinical picture. In one case the twitching was restricted to the cremasters, the testicles being kept in continual movement. The next day the abdominal muscles shared in the movements, and necropsy confirmed the encephalitis. The jerking sometimes simulated actual chorea. These "chorea" cases proved fatal. Neuralgic pains formed the main symptoms in some cases, pains in the spine, back of the neck and on pressure of the eyeballs. In some of the fatal cases there was no somnolency at any time. In one case the whole syndrome was reduced to moderate fever, persisting mental confusion and profound slumber for six weeks. There is always fever at the outset, but it may subside promptly. The patients sleeping calmly may even increase in weight during the disease. Necropsy shows that any part of the cerebrospinal axis may be affected, and not merely the brain. The lesions are extremely minute and may be merely microscopic hemorrhages, but they explain the polymorphism of the symptoms and their variability. The cases all fall into one of the four types, the lethargic, the motor excitement to actual chorea, or tetany, the paralytic, and the mental confusion type. Gabri cultivated what he thinks is *Micrococcus tetragenus* from his three cases. Fornara relates that hexamethylenamin in two of his cases caused spasm of the bladder with tenesmus and retention of urine, compelling its suspension. In one case parenteral injection of milk was followed by great improvement; the fever dropped by crisis and the patient roused from heavy sleep. Others reported cultivation of a gram-positive diplococcus, and confirmed the punctiform hemorrhages in sections of the brain. Fua described a case in a babe of 4 weeks, with ptosis, strabismus and coma, which, he says, sustain the assumption that lethargic encephalitis is a form of epidemic poliomyelitis.

Clinical Pictures in Influenza. A. Bertolini.—p. 1069.
*Lymphogranulomatosis. C. Cantieri.—p. 1072.
Pituitary Surgery. E. Aievoli.—p. 1080.

Purulent Pleurisy.—Dalmazzoni rejects local anesthesia for these operative cases on account of the danger from reflex action. He anesthetizes with the patient lying flat on his

back to insure the fullest possible expansion of the lungs, and then very cautiously turns him on his side with a cushion under the thorax to render convex the field of operation. His incision is 12 or 14 cm. long and follows the tenth rib, the center on a line with the middle of the scapula. He warns that to drain the pleura effectually we must not consider the cadaver but the position usually taken by the patient. He usually lies on the posterior hemithorax on the diseased side. About 3 cm. of the tenth rib are resected and more if necessary, but Dalmazzoni never rinses out the cavity nor introduces gauze into it, his reliance being on the efficient drainage and on keeping open the opening made. It is packed with gauze to insure this, and the opening is frequently cleansed with water and alcohol. He drains with a large tube 5 or 6 cm. long, traversed by another rubber tube, the transverse bar preventing the tube's slipping in too far. The drain could soon be removed and the drainage continued with a flat dressing, and the cure was complete in ten or twenty days. In twenty-two of his thirty cases thus treated the empyema was of influenzal origin. Lesions elsewhere were responsible for the deaths in the 9 per cent. fatal cases.

Lymphogranulomatosis.—Cantieri devotes nearly eight pages to the clinical and pathologic anatomic findings in a case, fatal in three months, in a man of 25.

*Hypothyroidism and Atrophy of Muscles. M. Pincherle.—p. 561.
*Agglutination of Proteus X in Various Children's Diseases. G. Fiore.—p. 598.
Special Pathology of Twins. C. Francioni.—p. 605; Reply. A. Borriño.—p. 606.

Hypothyroidism and Atrophy of Muscles.—Pincherle presents evidence to show the importance of the endocrine factor in the pathogenesis of defective nutrition and development of muscles. He describes with minute detail the case of a boy of 11, with unmistakable signs of thyroid deficiency from early childhood, actual congenital myxedema, on which became superposed progressive muscular atrophy. He has found only two analogous cases on record, and in one of them the coincidence was considered casual. In Pincherle's case the causal connection between the hypothyroidism and the muscular atrophy was brilliantly confirmed by the improvement under thyroid treatment. The atrophy was of the pseudohypertrophic type. The literature is reviewed, and the prospects of warding off or curing such muscular dystrophies by suitable organotherapy are extolled.

Agglutination of Proteus in Various Children's Diseases.—Fiore applied the agglutination test specific for typhus in from two to six cases of seven different diseases peculiar to childhood, and in eighteen other children with nephritis, acute rheumatism or gastro-intestinal disease. The response was constantly negative in all the forty-eight children tested with dilutions of from 1:200 to 1:10.

Rivista Critica di Clinica Medica, Florence

Oct. 25, 1919, 20, No. 43

*Tardy Osteoperiostitis with Inherited Syphilis. A. Varisco.—p. 505.

Tardy Osteoperiostitis with Inherited Syphilis.—The young woman had been apparently healthy, except for a few convulsions in infancy, until measles at 18. At 20 she complained of pains in the legs and large joints, and the latter began to enlarge in a few weeks, with a low continuous fever and drowsiness. The spinal fluid seemed to be normal. Not until the end of six months did the symptoms subside so she could leave the bed. After a few months of slight ups and downs, painful tumors developed in the crest of the tibia and other long bones and the clavicles, and numerous glands enlarged. After nearly a year from the first symptoms, a tentative course of mercurial treatment not only cleared up the diagnosis—the previously negative Wassermann reaction veering to positive—but resulted in practically a cure. There was nothing in the family history to suggest syphilis except the shape of the patient's teeth and a certain pigmentation of the face.

Nov. 8, 1919, **20**, No. 45

*True Infantilism. E. Bufalini.—p. 529. Begun in No. 44, p. 517.
Present Status of Cervical Ribs. Fornaseri.—p. 534.

True Infantilism.—Bufalini gives a detailed account of a case of true infantilism, the man of 20 presenting the complete physical and mental characteristics of a normal boy of 12. There was nothing to suggest endocrine disturbance or inherited taint. He theorizes to explain this type, ascribing it to an insufficiency of the primordial vital substance.

*Motor Plastic Amputations: Cinematization. G. Bosch Arana.—p. 621.
*Brain Tumors in Children. R. A. Rivarola.—p. 636.
*Influenza and Typhus. G. Sanguinetti.—p. 642.
*Endocrine Rheumatism. E. A. Lombardi.—p. 646.
Fluorene as Reagent for Aldehyds. L. Guglielmelli and A. Delmon.—p. 653.

Motor Plastic Amputations.—Among Bosch's thirty-three illustrations are some which show the peculiar looking stump of the upper third of the thigh as remodeled for cinematization; then the details of the artificial leg provided to utilize the muscular force in the loops of the stump, and, finally, the movements of the foot as the patient flexes and extends the knee by control from the muscle loops. The foot can be swung through an arc of 30 degrees. The man thus walks by the natural bending of the knee, and in two months has already learned to manage his artificial leg quite well. Bosch urges others to continue work in this line, dwelling on the benefit to society and to the state, as well as to the individual, from this utilization of muscular energy hitherto lost by the old systems of mutilating surgery. The prosthetic appliances for leg and arm which he uses were constructed under his directions.

Brain Tumors in Children.—Rivarola's article is based on nineteen personal cases and 120 from the literature. He was impressed with the length of the interval in others' cases between the first examination and the diagnosis of the location of the tumor, and the further delay after this before the operation. Except syphilomas, all brain tumors, he declares, should be removed no matter what their nature may be. Lumbar puncture is of no use, and exposes to serious mishaps. Radiography is also no help in the diagnosis, except with tumors of the sella turcica. The tuberculin and Wassermann tests are also useless for determining the nature of the tumor. He suggests that there may be a field here for radium treatment. Tuberculomas form about 50 per cent. of the cases of brain tumor in children, while syphilomas form barely 0.3 per cent. The cerebellum is the preferential site of the tumor in children. Brain tumors in children are easily enucleated as a rule. The physiology of the child's brain differs from the adult; certain centers are not yet anatomically formed, and hence the manifestations of their

functioning are lacking from the clinical picture of brain tumors as we see it in adults; owing to this, diagnosticians are often misled. The first objective symptoms noticed by the family are very important for the diagnosis, besides the cardinal symptoms, headache, vomiting, constipation and edematous optic disk or optic neuritis. These symptoms combined point to a brain tumor, and the fundus findings are always pathologic. Mercurial treatment may be pushed but no more than two or three weeks should be wasted on it, while the child is being watched for other symptoms. The question then is whether the tumor is in the cerebellum or in one of the seven main areas of the brain. Greater precision is not necessary as the whole of one of these areas is exposed, and it is easy to detect symptoms traceable to such a large zone. The cerebellar, frontal, rolandic, parietal and pedunculocerebellar zones are responsible for fully 80 per cent. of all brain tumors in children, and these areas yield the most instructive symptoms. Perhaps this is because these zones are the better irrigated and most active functionally. Hemianopsia along with disturbances in gait, noticed by the parents before occipital symptoms developed, point to the cerebellum, disregarding the occipital manifestations as these are probably due to compression from a distance. If before the general convulsions developed, there were convulsive spasms of the muscles of the neck and shoulders, the frontal lobe should be suspected. If the child complained of its ear along with the intense headache, examine the temporal lobe. More than in surgery elsewhere, an early diagnosis and immediate operation should be the rule. He found only one case of syphiloma on record. This was in a girl of 9, and necropsy after a year of absolutely ineffectual specific treatment revealed the gumma which could easily have been removed during the eighteen months after the first symptoms.

Influenza and Typhus.—Sanguinetti presents arguments to show that dengue, influenza and typhus are linked together like measles and scarlet fever, or typhoid and colon bacillosis.

Hypothyroidism and Rheumatism.—Lombardi describes an extreme case of endocrine rheumatism in a woman of 53, with prompt recovery under thyroid treatment.

*Viscosity of the Blood. H. Rodriguez Pinilla.—p. 17.

*The Urine and the Wassermann Reaction. J. Arijón Gende.—p. 18.

Viscosity of the Blood.—Rodriguez discusses the viscosity of the blood and its bearing on a number of biologic problems.

The Urine and Hemolytic Tests.—Arijón tabulates the findings in a number of comparative tests made with the blood serum and the urine for deviation of complement. Nothing was found to indicate the presence of an antigen in urine even in cases with pronounced Wassermann reaction in the blood serum. It is theoretically possible, however, he admits, for certain urines to behave like an antigen in the Wassermann test; some of the colloids in the urine, when sufficiently concentrated, might act in this way.

A Third Form of Paratyphoid.—Lewy and Schiff describe a third form of paratyphoid that they encountered in Asiatic Turkey. Neukirch, and, at about the same time, Weil, furnished the first information in regard to the causative agent (the Ersindjan bacillus) in 1915. Schiff first isolated this

bacillus in 1916 in Aleppo, Syria. Up to September, 1918, Lewy and Schiff had seen approximately eighty cases definitely established by bacteriologic examination. Very light infections were common among the native population. However, cases were observed, especially among the German soldiers in Palestine, that developed a protracted fever of a very irregular type and often ended fatally. The *Ersindjan* bacillus produces typically a septic infection that is characterized by remittent fever, bacteremia, a septic blood picture, embolic abscesses; hemorrhagic inflammation of the kidney, the intestine and the liver; minute abscesses and necrosis of the liver and kidneys, hemorrhages of the serous membranes, and a septic spleen. Accumulations of bacteria in certain parts may produce septic meningitis, septic pneumonia or pyelitis. While a septic course is not typical for paratyphoid A and B, it is the rule in the paratyphoid of which *B. Ersindjan* is the causative agent. Although this infection is very commonly associated with dysentery, influenza or malaria, it nevertheless seems to be a distinct morbid entity. The mode of transmission is probably by direct contact with infected persons, though it may possibly occur through eating certain foods. So far there have been no authentic cases of the infection in Germany. The *Ersindjan* bacillus received its name from the place where it was first isolated. Its resemblance to *Bacillus suispestifer* is marked.

Autogenous Vaccine Treatment in Diplococcus Infection of the Urinary Organs.—Pfister and Böhme give their experience with a micro-organism, a diplococcus, found in the urine of a patient who complained of headache and pain in the sacral region. The urine had a whitish tinge and albumin was present. The patient improved but the urine did not clear up. Following a "cold," the headache and back pains came on anew. In the urine sediment many red and white blood corpuscles were found; also an unusual number of gram-positive diplococci. A prostatitis was present, with many pus cells, but no bacteria. Functional tests of the kidneys revealed a diminished power of secretion and concentration. The Wassermann test was negative; also roentgenologic examination of the kidneys. Blood pressure was 111-121; albumin content, 0.1-1.0 per cent.; quantity of urine normal. The residual nitrogen in the blood was markedly increased. The diagnosis was chronic pyelonephritis (without casts), with aseptic prostatitis. An autogenous vaccine was prepared. The diplococcus was cultivated and a pure culture secured. In the blood of the patient agglutinins in the titer ratio of 1:500 were found. Immediately after the vaccine treatment was begun, the urine cleared up, the diplococci disappeared from the urine. The writers regard the case as interesting as showing that autogenous vaccine treatment may be successful in infections of the urinary organs other than those produced by *B. coli*. The identity of the diplococcus could not be fully established. It seemed to be a new invader.

Value of Physical Exercises in the After-Treatment of Internal Diseases.—Quincke emphasizes the great value of graduated physical exercises in the after-treatment not only of diseases affecting the joints and muscles but also in pleuritis, enteroptosis, chronic constipation, and in practically all internal diseases. Only a few patients need special exercises

adapted to their peculiar condition, but all convalescents will make more rapid and surer progress toward health if they are required regularly to go through such setting-up drills as are in use in the army and in the gymnasiums. Of course, the amount and the character of the exercise will depend on the condition of the convalescent. The first exercises after recovery and after rising from a sick bed should be taken alone, but after convalescents have partially recovered their strength there is added value in exercises carried out in groups or classes. Such exercises not only restore a normal blood circulation, but they are needed to give control of bodily movements, for long confinement to the bed will often have impaired the motor apparatus.

A More Direct Method for Testing the Faradic Excitability.—Erlacher gives a preliminary report of his investigations on the possibility of testing in a more direct manner the faradic excitability of paralyzed muscles. Instead of testing through the skin, as heretofore, he inserts about 2 cm. apart, two fine needles, previously immersed in alcohol, into the skin which has been disinfected with iodine or alcohol, and pushes them from 8 to 15 mm. deep into the muscle to be tested. The two needles are then connected with the respective poles of the faradic current by an uninsulated, soft copper wire, which is wound spirally around each needle and soldered to it. A simple form of interrupter is inserted. Weak currents such as are scarcely felt when applied to the tongue produce a distinct twitching of the muscle fibers lying between the two needles. Somewhat stronger currents cause a puckering of the area contiguous to the excited muscle. Still stronger currents—but not nearly so strong as are required in the percutaneous testing—produce a distinct contraction. As a rule, it is not necessary, when this method is used, to increase the current until a motor effect is produced, as the twitching of the muscle fibers will usually be sufficient. Muscles that by the percutaneous method were declared to be completely paralyzed were found to react when stimuli were applied by this direct method. It is evident that death of muscular tissue—from a faradic standpoint—does not take place so quickly nor so early as has been heretofore assumed. Erlacher claims, therefore, greater diagnostic value for his more delicate method of muscle testing.

Rhythmic Pressure and Release in the Cederschöld Method of Massage.—Schmidt announces, after over ten years' experience, that the Cederschöld method of manual massage is the most conservative and at the same time the most effective. He considers it the most conservative method because the soft parts that may have been injured are not exposed to further injury as is the case when they are kneaded, stroked and rubbed. It is effective because by the systematic application and removal of pressure as brought to bear on the periphery of a limb, a suction and pumping action is brought into play in the most excellent manner; congestion in the lymph glands and in the blood vessels is counteracted, and extravasated matter is more readily absorbed. By this method, in large cicatricial areas vascularization is stimulated and function is restored, whereas by frictional massage delicate tissues may be torn, and new, though slight, lacerations be produced. In applying rhythmic pressure to an upper extremity, the arm is encircled by the hand of the operator and the pressure is gradually increased until the arm is tightly grasped; the pressure is then slowly removed, and the operator advances a hand's breadth centrad, and proceeds as before until the whole arm has been thus massaged. In massage of the lower extremities and the trunk, both hands are used. The extensors and the flexors may be treated separately, and it is often convenient to use the bones as a base. Cederschöld, following the example of Rosthorn, has found that rhythmic pressure massage may exert a favorable influence even in mental diseases and in depressive states.

Zentralblatt für Chirurgie, Leipzig

Jan. 31, 1920, 47, No. 5

*Blocking the Splanchnic Nerves. M. Kappis.—p. 98.

*Prevention of Caustic Strictures. F. Bonhoff.—p. 99.

*Wire Suture. A. Knoke.—p. 99.

*Access to Deep Phlegmon of the Axilla. W. Levy.—p. 101.

Blocking the Splanchnic Nerves.—Kappis remarks that Braun's method of injecting the anesthetic from the front confirms the ideal anesthesia of the viscera when the splanchnic nerves are blocked. Braun introduces the needle, through the laparotomy incision, along the lower margin of the liver, injecting 100 c.c. of a 0.5 per cent. procain-epinephrin solution, distributed on both sides of the aorta near the first lumbar vertebra. Kappis makes the injection from the rear, just below the twelfth rib, distributing the anesthetic by moving the tip of the needle 3 cm. upward and then 3 cm. downward, about 0.25 to 0.5 cm. from the spine, thus spreading the 50 c.c. on each side over a larger area than by his previous technic (mentioned in these columns, Feb. 21, 1920, p. 568).

Prevention of Strictures from Caustic Action.—Bonhoff relates that no stricture has developed during the two years since in a case of caustic injury of the esophagus in which he introduced at once a retention sound. It was worn until healing was complete, and it warded off cicatricial retraction of the walls. The caustic was ammonium chlorid (salmiak) in this case. Roux of Lausanne has recently reported similar success with this preventive catheterization.

Wire Suture.—Knoke has been using wire recently as other suture material is so scarce and poor. A method that has proved very satisfactory is to draw the wire through the two lips and cut it off, each end held with forceps. As many wires as are needed are introduced, the row of forceps on each side keeping them from slipping out. Then the ends of each wire are twisted together over a long roll of gauze by turning the corresponding forceps around each other.

Deep Phlegmon in the Axilla.—Levy expatiates on the difficulty of diagnosing these deep phlegmons which often prove fatal, as in two cases reported. There may be no local symptoms except a slight tenderness on the front of the shoulder, or a sensation of heaviness in the arm, or there may be nothing to call attention to the process except a history of some insignificant wound on a finger a week or two before, followed by high fever and general depression. If one operates on these findings alone, the results may be disappointing, but this should not deter from intervention when the general condition is grave. The chief danger is the possibility of the spread of the process. Some surgeons incise along the lower margin of the pectoralis major, but Levy found that the process, in one case described, could be fully exposed only by incising from the clavicle to and beyond the insertion of the pectoralis major on the upper arm, and cutting this muscle close to its insertion, and also cutting the pectoralis minor. These muscles heal readily without appreciable functional disturbance, he has found. This opens up the phlegmon, and its spread can be traced in three directions.

Sarcoma of Thyroid and Pancreas.—Van Rijssel found a tumor in the thyroid in 4 out of 650 cadavers; in another cadaver there was metastasis in the thyroid; in another the thyroid contained an adenoma and weighed nearly 73 gm. A seventh cadaver presented a rapidly growing primary giant-cell sarcoma in the thyroid with metastasis in the lungs. He has encountered another case of sarcoma in the thyroid in a woman of 61, inoperable within three weeks of the first signs of trouble, and death in less than six weeks, from multiple metastases. Both these cases confirmed the saying that a malignant tumor in the thyroid does not move with the trachea during swallowing, as simple goiter does. The cancer grows to adjacent organs. Among the total 6,400 cadavers examined there were 733 with carcinomas and 105 with sarcomas. The pancreas was the seat of the malignant disease in 25 cases, including only one of sarcoma. This was in a man of 25 and the sarcoma was of the giant cell type.

Quincke's Edema.—Bolten reports a case in which attacks of migraine were accompanied with a set of symptoms which can be explained only as intra-abdominal angioneurotic edema appearing and subsiding with the migraine in a woman of 40.

*Prognosis with Influenzal Pneumonia. V. Bie.—p. 175.

*Silver Salvarsan. H. Boas and A. Kissmeyer.—p. 191; Idem. A. Korsbjerg.—p. 196.

The Prognosis with Influenzal Pneumonia.—Bie states that 94 per cent. recovered of his 269 patients with unilateral pneumonia with a respiration rate of 34 or below, while only 54 per cent. recovered of those with a rate of 40 or above. With bilateral "flumonia," 74 per cent. recovered of the 287 with respiration of 39 or below and only 33 per cent. of the forty with a rate 40 or above. The total mortality in this group was 35 per cent. The respiration rate is thus an important element in the prognosis. The mortality was 35 per cent. in the pneumonia cases with albuminuria, but only 12 per cent. in those without albuminuria. The highest temperature noted was in a man who recovered; the lowest in one who died. These and other data mentioned show that the temperature has little value for the prognosis; the pulse is more instructive. All who died had a comparatively high pulse rate, 109 or 110. All the above records refer to the day the patient was brought to the hospital, or the next day. Bie's article is based on 1,653 patients, and he calls attention to the fact that not less than 15 per cent. of those received in the hospital during the later months of the pandemic had had the disease during the early months, and this was the third attack within a year in some.

Silver Salvarsan.—Boas and Kissmeyer relate that Kolle presented them with 400 tubes of silver salvarsan, and they applied it in treatment of sixty-two syphilitics, with results that show it is at least the equal of old salvarsan, while it is much more soluble. Korsbjerg reviews what others have published on the subject. His own experience with it in thirty-two cases left a very favorable impression. He says that the drug contains 14 per cent. silver and 22.5 per cent. arsenic, and has a catalytic action.

OPERATION AND REOPERATION FOR GALLSTONE DISEASE*

JOHN B. DEEVER, M.D.

WITH A REPORT ON PATHOLOGIC RESEARCH BY

STANLEY P. REIMANN, M.D.

Director of Pathologic Laboratory, Lankenau Hospital
PHILADELPHIA

The question of recurrence of symptoms after surgical treatment of affections of the gallbladder and the biliary passages is one that has been much discussed during the past decade, and one which I believe will bear further consideration.

In 1916, reporting on more than a thousand operations on the gallbladder and the biliary passages in my service at the Lankenau (formerly the German) Hospital of Philadelphia, I found that 4.07 per cent. were reoperative cases (some of the patients having had three operations). Among 800 cases coming under my care in the same hospital since January, 1916, it appears that 8.5 per cent. (seventy cases) were secondary (there were also a few tertiary) operations. Confronted with this increase in recurrence, we naturally turn to seek the cause.

Of the recent series, fifty-one patients were originally operated on elsewhere by other surgeons, the remaining nineteen having been operated on by me at the Lankenau Hospital.

In thirty-six of the fifty-one, recurrence took place after a cholecystostomy and fifteen after a cholecystectomy. The longest interval between operations was fifteen years. This patient (reported in a previous communication), in fact, had been operated on twice before coming under my care. The first operation—cholecystostomy—for the relief of gallstones had been done seventeen years previously, followed two years later by a choledochoduodenostomy and repair of an incisional hernia. At the third operation numerous adhesions were found about the anastomosis, the dilated common duct contained numerous stones as well as foul smelling grumous material, and the ampulla of Vater was constricted.

The information regarding the condition found at the primary operation is not complete for all the cases of this group. Among those for which data are at hand, the shortest interval between operations was seven months. The symptoms in this case recurred three months after the cholecystostomy. At the second operation, in addition to a mass of adhesions, stones had again formed in the gallbladder, and stones were also found in the common duct. The gallbladder was

then removed, and the common duct emptied and drained. In another case—empyema—in which the colon bacillus was cultivated from the pus, the symptoms returned about seven months after the draining of the gallbladder. At the secondary operation—cholecystectomy—the pancreas was found chronically and markedly diseased.

The average interval between operations in this group was about five years and nine months, the average period of freedom from symptoms being about two years and three months.

In the fifteen "ectomized" cases, in addition to adhesions which were present in all but one, reoperation was necessitated by the presence of fistula in four instances, common duct obstruction, stone or stricture, nine, and pyloric obstruction three. Three of the patients in the group failed to derive any benefit from the primary operation; of the others, the longest interval of freedom from symptoms was four years, the average being about four months, and the average interval between operations about eight and a half months.

In considering my personal cases (those in which the primary and secondary operations were done by me), I find that in eight the symptoms recurred after primary cholecystostomy, one after choledochostomy, and ten after cholecystectomy, or 1.3 per cent. after removal and 10 per cent. after drainage operation.

Excluding the fifty-one cases of the first group (in which the patients were primarily operated on elsewhere), a primary cholecystectomy was performed in 611 and cholecystostomy in seventy-eight cases; other primary operations consisted of cholecystoduodenostomy, 27; choledochostomy, 11; choledochoduodenostomy, 1; exploratory, 16; pancreatostomy, 4, and duodenotomy, 1. The last represents a case of carcinoma of an aberrant pancreas found in the duodenum and excised.

The longest interval between operations in the drained cases was fourteen years, the shortest one month, with an average of six years and four months, while freedom from symptoms averaged three years, the longest period being thirteen years and the shortest one month.

Of the fourteen patients whose gallbladders were removed, five remained well for a period varying from two months to two years, two were not benefited by operation, and seven required secondary operation during convalescence.

Taking this recurrent series collectively, we find the pathologic condition most frequently noted after operation to be adhesions (noted thirty-nine times), while the most potent cause for return of symptoms after operation proved to be stone in the gallbladder and ducts (twenty-six), which coincides with our pre-

* Read before the Brooklyn Surgical Society, Feb. 5, 1920.

vious experience. Next in frequency, in the order named, were: persistence of infection, cholecystitis, seventeen; fistula, eleven—biliary, nine, duodenal, two; common duct obstruction, ten; chronic pancreatitis, eight; pancreatic lymphangitis, six; cholangitis, six; pyloric obstruction, five; dilatation of ducts, five—common duct, four, cystic duct, one; carcinoma, four—pancreas, two, gallbladder, two; stricture of the ampulla of Vater, two. Some of the cases presented one or more of the conditions mentioned.

ADHESIONS

It thus appears that adhesions were noted in 52 per cent. of the recurrent cases. The damaging and symptom-producing adhesions are principally those that form after cholecystectomy, and bind the duodenum, in some instances with the pylorus, the great omentum, and not infrequently, the hepatic flexure of the colon to the under surface of the liver. The symptoms caused by this deformity do not as a rule make their appearance for some time after the operation, or until they are in the process of organization and have reached the stage of contraction. There are exceptions to the rule, however, as for example persistent vomiting coming on from one to two weeks after operation, making it impossible to nourish the patient by mouth and where lavage demonstrates considerable gastric retention. I have seen this complication several times and for its relief have been obliged to do a posterior gastro-enterostomy, after which convalescence was rapid and uninterrupted.

It is generally admitted that gastro-enterostomy has its greatest usefulness in pyloric obstruction, and ulcer of the duodenum and stomach, but the operation also has a distinct place in a certain class of complicated gallstone cases. The very fact that gallstone disease, without operation, or after operation, can cause a condition requiring gastro-enterostomy should of itself be enough to do away forever with the expression "simple gallstones."

Ulcerative communication between the biliary passages, the stomach and the duodenum, not infrequently seen by those of us operating on patients previously operated on for gallstone disease, is a well-known phenomenon. That this can and does result in obstruction to the onflow of the stomach contents which, I am sorry to say, is not always recognized by the diagnostician, I know to be true.

Deferred action in these cases is inadvisable, and medication ineffectual. Rectal alimentation is a makeshift. Filling the rectum with sodium bicarbonate and glucose is not a very pleasant procedure, nor does it do any good except for the sorry consolation it may give of having done something for the patient, who usually dies.

In late cases of duodenal and pyloric obstruction I find it safer to do a posterior gastro-enterostomy than merely to separate adhesions, safer in that it is more permanent and less likely to require further operation. We all know that adhesions tend to recur and that nothing will prevent their formation if the raw surfaces cannot be covered with peritoneum. I have mentioned duodenal obstruction before pyloric, as in my experience the duodenum is more often obstructed than is the pylorus. In an old case of extensive adhesions in which the viscera normally in relation with the gallbladder are matted into an almost unrecognizable mass, the operation of separating and covering

the denuded surfaces is likely to be a very difficult procedure attended with great risk of tearing the duodenum and in some instances the colon. I have had this happen, and have had to resect the torn duodenum with the pylorus and make a posterior gastro-enterostomy.

The comparative ease with which the duodenum can be repaired so as not to expose the patient to the risk of a duodenal fistula, a most dangerous and difficult proposition with which to deal, reads well and sounds well, but the seriousness of it must ever be borne in mind. Occasionally after separating the adhesions and disentangling the viscera I interpose a portion of the great omentum between the liver, the duodenum and the pylorus, and have had no cause to regret the maneuver.

When the removal of the gallbladder is carefully and anatomically done, few adhesions should follow the operation. The gallbladder being fully exposed, the neighboring viscera well protected and kept out of the way by properly placed moist gauze pads, not gauze towels (held in place by retractors), with the gallbladder held taut, as it were, the first step in the operation is the opening of the right free border of the gastrohepatic omentum and the identification of the common, cystic and hepatic ducts and the cystic artery, which, with the hepatic artery, may be found anomalous. Anomalies of the ducts or arteries make little difference to the operator who knows his anatomy and does the operation in this manner. Lack of care in grasping the cystic duct with hemostatic forceps or the cystic artery, if perchance it has been severed, is a frequent cause of injury to the common or hepatic duct with stricture or obstruction of the duct as a result. I refer to this later. For the occasional operator, therefore, I would suggest a drainage operation and not removal of the gallbladder. It is better for the patient to run the risk of recurrence of gallstones than be left with either a damaged common or hepatic duct, a condition I have had to deal with a number of times, and which warrants me in being very emphatic on this subject. In doing many hundreds of operations for gallstone disease, one becomes more or less familiar with the danger signals. I have never taken any stock in the theory of biliary duct angulation due to adhesions or the traction of a movable kidney as the cause of symptoms of gallstone disease, particularly jaundice, because I have not encountered any instances of the kind in my numerous operations.

That adhesions form after a drainage operation is true; but they are neither so dangerous nor so productive of serious trouble as are the adhesions that follow removal if the operation is not very gently and carefully done.

NEW STONE FORMATION

The second most common cause of recurrence of symptoms is the presence of stone or stones. With few exceptions the stones found at the second operation were probably present at the primary operation but were not detected. The time elapsing between the two operations, or perhaps a third one, has a bearing on the subject. Even though, at the first intervention, all of the stones that were palpable to the finger or that could be removed with the scoop were taken out, subsequent stone formation occasionally takes place. It may happen that small granules of stone adhering to the mucosa of the gallbladder are present in the neck of the latter, or in the common or the hepatic duct, or

its ramifications, and subsequently develop into one or more good-sized stones. Often after opening a gallbladder that has been removed I have seen such tiny stones adhering to or embedded in the mucosa. How long a time is required for these stones to develop cannot be definitely stated. Some of the patients returned in a few months, others remained well for thirteen years.

When a number of years have elapsed between the original operation and the reoperation there is every reason to believe new stone formation has taken place. And in nearly all cases, as before the first operation, a history of infection will in all likelihood be obtained for the interval between operations. The sequence of events in gallstone formation I believe to be: infection, inflammation, obstruction to drainage, retention—bile stasis—proliferation of epithelium, formation of cholesterolin, etc. In recurrence after drainage operations we know that it is not uncommon to find stones. For the recurrences after removal of the gallbladder, with the subsequent presence of stone or stones in the common duct or the hepatic duct, the most plausible explanation is that a small stone located high up has descended and has lodged either in the hepatic or in the common duct and there increased in size until it is too large to be passed and has thus caused obstruction. I have observed this in a number of instances; in fact, I have seen it occur three times in the same patient before obtaining complete freedom from recurrence. In some of these cases I have been able to predict the probability of a return of symptoms, especially when I had been able to feel a stone high up in the duct, but could not remove it; or when, having brought the stone into the hepatic duct, it has slipped away and has been lost; or when I have found the ducts filled with sandy material, and when, after removing as much of the latter as possible, with the ducts laid open as far as possible, I have instituted prolonged drainage. Even in these cases it is no surprise to learn of subsequent common duct obstruction by stone.

CHRONIC CHOLECYSTITIS

The third most common cause of recurrence—persistence of infection—in the shape of chronic cholecystitis, I believe to be inexcusable. First of all, the frequency of recurrence from this cause lends support to the theory that noncalculous cholecystitis is a clinical entity distinct from the calculous gallbladder inflammation, and justifies removal of the gallbladder in such cases. Furthermore, it is inexcusable, in view of the fact that dyspepsia or chronic indigestion is not a clinical entity of itself, but the accompaniment or the result of a greater or less degree of a pathologic condition in one or the other of the abdominal viscera, and that next to appendicitis, the most common type of indigestion is gallbladder dyspepsia. The differentiation between the two is not always possible except by operation, and even then one cannot always tell whether or how far the appendix is also responsible for the symptoms, in those cases in which the gallbladder has undergone pathologic changes. Owing to this uncertainty, it becomes necessary in the majority of cases to remove both the appendix and the gallbladder. This brings up the question of priority of responsibility for the symptomatology. You are all, no doubt, aware of my conviction that the guilt for most of the upper abdominal ailments lies primarily within the appendix, although I may say in passing that I am

not unmindful of other possible sources of focal infection. How rarely do we find an appendix, removed as a routine procedure in our abdominal operations, that is not diseased, and markedly so, in most instances?

Chronic cholecystitis is not always difficult to diagnose; it can generally be recognized by a proper correlation of the history and the results of physical examination, especially local tenderness and more or less local rigidity. In cases of doubt we can call on the roentgen ray and various laboratory methods of examining the condition of the stomach, duodenum, pancreas, intestinal tract, etc. Having once arrived at the diagnosis, prompt action is essential. Dilly-dallying with medicines, in my experience, not only profits the patient nothing, but rather favors further visceral involvement and the possible extension of the process by way of the lymphatics or the blood stream to other important organs. This possibility is well illustrated by the researches carried on in the pathologic department of the Lankenau Hospital under the able direction of Dr. Stanley Reimann, whose investigations I have incorporated in this paper. This interesting work of Reimann, I believe, should settle the question of medical versus surgical treatment of persistence of infection in chronic cholecystitis and its responsibility for so large a percentage of recurrences after cholecystostomy.

OTHER CAUSES OF RECURRENCE

The recurrent series includes ten cases of noncalculous common duct obstruction. Six were due to stricture, three to scar tissue, and one to ulceration.

The principles involved in the treatment of obstruction of the common duct by stricture, scar tissue and ulceration are practically the same. In stricture of the common duct, whether annular or linear, the duct is laid open to the extent of involvement in the line of the duct, and drainage established by the T-tube; for annular stricture involving a wide portion of the duct resection and end-to-end anastomosis is best; or if the stricture is too near the duodenum to make this feasible, anastomosis of the proximal end into the duodenum and closure of the distal end can be done, this layer of suture being reinforced by the great omentum. These operations I have done a number of times with good result.

In ulceration of the duct, the treatment is practically the same as for stricture. Obstruction of the duct by scar tissue occurs where the duct has been cut away, and the scar tissue forms in the shape of a cord connecting the two ends. Under these circumstances the most difficult portion of the operation is to identify the lower end of the duct. The proximal end, unless well within the transverse fissure of the liver is, as a rule, not so difficult to identify if we aspirate with the hypodermic syringe. When the greater portion of the duct is destroyed, it is best to mobilize the duodenum and anastomose the proximal end to the duodenum. Sometimes the T-tube or a small piece of rubber tubing introduced into the end of the duct and the duodenum can be used to advantage in the anastomosis. I always reinforce the anastomosis with the greater and the lesser omentum. This, however, is difficult and trying surgery, calling for the greatest gentleness of manipulation, patience and utmost skill, ingenuity and judgment.

Biliary fistulas, of which there are nine in the series, are practically all the result of stone in the common duct, and can be obliterated only by relieving the

obstruction. This type of fistula rarely is due to malignancy, but when attributable to such cause is nearly always irreparable. Quite as serious is duodenal fistula, reported twice in the series. Resection, pylorotomy and gastro-enterostomy are the procedures indicated, but they are not always possible and not always successful, owing to the depleted condition of the patient.

It will be noted that chronic pancreatitis and chronic pancreatic lymphangitis were the cause of twelve recurrences. While pancreatic lymphangitis is frequently corrected by removal of the gallbladder, this does not apply to chronic pancreatitis, particularly in the long-standing cases. Although I have so often called attention to the importance of pancreatic lymphangitis as a forerunner of chronic pancreatitis, I cannot refrain from mentioning it once more as a factor to be seriously reckoned with in gallstone disease surgery. Drainage, of course, is the *sine qua non* in the presence of chronic pancreatitis, and, if, owing to diseased condition of the gallbladder and the cystic duct, cholecystotomy is not possible, drainage must be established through the common duct.

Duct drainage is also indicated in cholangitis, the result of gallstone disease, and must be continued for a number of weeks. I have known patients who have carried a drainage tube in the common duct for as long as four years; it is only in very obstinate cases, however, that such prolonged drainage is required. The simplest means of accomplishing this is by way of the gallbladder; but when this is not feasible, drainage through a cholecystoduodenostomy or by way of the common duct will be necessary. Incidentally, I may remark that biliary cirrhosis may result from chronic cholangitis if not given the benefit of radical surgery.

Dilatation of the common duct in the presence of an irremovable cause is best treated by a choledochoduodenostomy—not by any means a very difficult thing to do with the duct enlarged.

Benign stricture of the papilla of Vater, which is not infrequent, I have always been able to correct by dilatation through an incision of the common duct.

Carcinoma of the head of the pancreas, as well as carcinoma of the ampulla of Vater, or the common or hepatic duct cannot always be differentiated except by opening the abdomen; nor can the differentiation of obstruction of the common duct by a silent stone always be differentiated from malignancy. I have seen a number of confusing cases which were cleared up only by operation. Carcinoma of the gallbladder is another one of the uncertain diagnoses, except in the presence of a palpable swelling which can be identified, or perhaps by roentgen-ray demonstration. It is worth mentioning that the majority of cases of carcinoma in which I have operated have been associated with stone; furthermore, I have no hesitancy in saying that I believe persistent cholecystic infection is primarily the responsible agent in the causation of this most unfortunate condition. It may not be out of place for me to mention a case of carcinoma of the fundus of the gallbladder that had not metastasized, but was adherent to the hepatic flexure of the colon, indenting the colon to such an extent that the roentgen ray seemed to indicate carcinoma of the bowel. This patient has remained well for more than two years since the operation (cholecystectomy).

The great variance between recurrences after radical surgery of the gallbladder and those that take place

after conservative surgery leads to the manifest conclusion that radical treatment gives the greater prospect of a permanent cure. Perhaps if the work recently reported by Vincent Lyon¹ of Philadelphia on the physiologic drainage of the gallbladder based on Meltzer's theory of contrary innervation can be developed into a more practical one—practical in the sense that any but the highly trained specialist can make use of it—we may obtain a valuable aid in early diagnosis and the possible prevention of the serious consequences of biliary stasis. For the present, however, radical surgery, although it falls short of being ideal surgery, is the best means we have of removing a pathologic condition and its pernicious effects. "If thy right hand offend, cut it off."

PATHOLOGIC REPORT BY DR. REIMANN ON RELATION OF STREPTOCOCCUS TO GALLBLADDER DISEASE

In classifying the pathologic histology of gallbladders, we have recognized an interstitial involvement of both acute and chronic nature in by far the large majority. Simple involvement of the mucosa was seldom encountered. The interstitial involvement, that is, infiltration of either acute or chronic inflammatory products into submucosa, muscularis and peritoneum, means only one thing—that organisms or their toxins or both are present in the walls of this organ. This picture makes plain the reasons for the frequent peritoneal adhesions, pancreatic lymphangitis and lymphadenitis, and chronic pancreatitis. Infection, of course, in the largest proportion of cases comes from within the lumen of the gallbladder.

A direct way of approaching this subject is afforded by the method developed by Rosenow and his associates. It consists of removing surface infection by either washing the organ, taken directly from the hands of the surgeon, in large volumes of saline solution, or dipping it momentarily in boiling water, then grinding it up in a meat grinder, and triturating with sand and saline solution. This procedure is carried out in a specially constructed box which allows of sterilization. The ground-up tissue is then planted in special mediums. Rosenow's results have indicated the presence of streptococci in the walls of the gallbladder as well as in other organs.

Forty-five gallbladders were treated by us in this way, and streptococci, all of the *S. viridans* variety, were found in nine instances, or 20 per cent. The pathologic examination of these gallbladders disclosed that all had a marked interstitial involvement. In more than half, there were acute changes engrafted on obvious preexisting chronic ones. Seven of the nine contained calculi. Other organisms were detected in many; but, since the discovery of streptococci was the main object, these were not definitely identified. In the other thirty-six specimens, practically half showed lesions that were confined entirely to the mucosa. The others showed more or less interstitial infiltrations of a chronic nature. Four showed acute involvement as well.

Surgical and pathologic experience demonstrates over and over again that in most instances the gallbladder in an operative patient has been the subject of at least several acute inflammatory processes. In a number, however, there has possibly been present a chronic, slowly progressing inflammation from the start.

1. Lyon, B. B. V.: Diagnosis and Treatment of Diseases of the Gallbladder and Biliary Ducts, J. A. M. A. 73:980 (Sept. 27) 1919.

The clinical experience is that a gallbladder which has once given trouble and recovered without operative interference will, in a large majority of instances, make its presence known again, usually in a more unfavorable way. This is quite reasonable when streptococci can be so easily demonstrated in the walls of at least 20 per cent. (in Brown's series in 50 per cent.). The ability of streptococci to remain latent for long periods of time is too well known to require emphasis. A scheme of treatment based on the laws of contrary nervous innervation must take this infection of the walls into very serious consideration. The instillation of magnesium sulphate and other such materials by tube into the duodenum may cause the gallbladder to empty itself, and thus be of advantage in draining infection from within the lumen of the organ. It seems unlikely, however, that infection within its walls can be removed by this means.

The question of elective affinity of these streptococci was investigated, and careful examinations were made of the gallbladders of rabbits in which recovered human streptococci were intravenously administered. It was recognized that rabbits are, on the whole, somewhat resistant to streptococci. The organisms were isolated from the human gallbladders, were suspended in saline solution, and injected intravenously into a number of differently controlled animals. Two special sets were used: one was presumably normal, and in the other a point of lowered resistance was induced by pinching the gallbladder with a hemostat. None of the animals died from the injection of streptococci. They were killed at various intervals, and the organs and fluids examined and cultures taken. No streptococci were recovered from any specimen in any case after the second day after injection. They were recovered, however, as a routine, in all the organs and fluids in animals killed on or previous to the second day. These included the gallbladder, bile, liver, kidney, heart's blood and spleen. Cholecystitis was not present grossly or microscopically in any of the previously uninjured gallbladders. The time allowed to elapse between operation and injury of the gallbladder, and the injection of the streptococci, varied from immediately to two weeks. After several days, recovery from the operation, as evidenced by the behavior of the rabbit, was perfect. Microscopically, these injured gallbladders showed the usual processes of necrosis to fairly complete organization at the site of injury, but no especial lesion beyond this zone of reaction.

From the whole series of experiments, the conclusion must be reached that the particular streptococci recovered from human gallbladders and injected intravenously into rabbits showed no elective affinity for the gallbladders of the animals; at least not with one injection of what seemed an adequate number of organisms.

This conclusion in itself, however, does not negative the importance of the streptococci in the human gallbladder. It is only a fact in the biology of the organisms. Their importance in the particular human being from whom they were recovered cannot, of course, be positively evaluated; but the following points may well be remembered:

With streptococci in the gallbladder, a chronic toxemia may be present for long periods of time; a constant stimulus for lymphangitis and connective tissue proliferation is present, and an opportunity for a general bacteremia is always at hand.

IDEALS AND THEIR FUNCTION IN MEDICAL EDUCATION *

GEORGE E. VINCENT, PH.D., LL.D.

President, Rockefeller Foundation

NEW YORK

The influence of the war on medical research, public health and medical education has been notable. Medical army officers of different nations have been in close association; research councils have exchanged suggestions and ideas; investigation has been stimulated; new possibilities of immunology have been discovered; important advances in surgical technic have been made.

Public health policies have been profoundly affected; camp sanitation has been carried to higher levels of achievement; the American army in Europe made a new record in the control of venereal diseases. The League of Red Cross Societies represents a movement in the interests of preventive medicine on an international scale. The work of the International Health Board in many countries has played an appreciable rôle. In all this, standards and methods of medical education have been necessarily involved.

Evidences of an almost universal interest in the training of physicians and public health officers accumulate. The British "unit" plan, which, with the opening of this year and under the auspices of the board of education, is being given a trial in four medical schools of London, is a significant experiment. In Belgium there is agitation for a reorganization of medical training under the auspices of the University of Brussels. Pathology and public health departments have been introduced in two medical schools in Brazil, and are influencing the other divisions of these institutions. A strike of medical students in Lima, Peru, against the alleged inefficiency of professors in the medical school is a symptom of the times. In China a modern medical school is being opened in Peking under American auspices. At Tsinanfu and Changsha, progress is being made. The University of Hongkong has a program for the modernizing and development of its medical department. The Chinese government medical schools are giving evidences of awakened interest and of improved methods. The Siamese government is seeking cooperation in the creation of a medical school in Bangkok. In the Near East there are several projects for new centers of medical teaching. Medical students are coming to the United States in increasing numbers from Japan, China, Czechoslovakia, Poland and Brazil.

IDEALS OF MODERN MEDICAL TEACHING

In order to measure achievement and to guide progress there is need of ideals or standards by which to appraise existing institutions and methods. Without tests of this kind there is danger that opportunism, provincialism, even a narrow nationalism, will prevent the development of medical education on a broad, international basis. To be of value, ideals must not be merely *a priori* and abstract aims: They must be rational projections of tested experience; they must combine, in one organic whole, elements each of which has somewhere proved its value. For example, the American type of medical education has incorporated features from the German laboratory institute, from the English clinical clerkship, and from other sources.

* Read before the Annual Congress on Medical Education and Licensure, Chicago, March 1, 1920.

The service which ideals and standards can render has been conspicuously illustrated by the Carnegie reports on medical education in the United States and in Europe, and by the activities of the Council on Medical Education of the American Medical Association. Thanks to these agencies, the main outlines of an efficient system of medical education have been worked out and generally accepted.

It is well to recognize the relativity of ideals. In human institutions there are no absolute standards. The highest ideal may be approximated in a few medical schools in which methods may be tested and leaders trained; but it would be a serious mistake not to recognize various degrees of achievement. The influence of local conditions, the possibilities of economic support, relations with other university units, must be taken into account. All that can be confidently affirmed is that some institutions fall below any standard that can be recognized as guaranteeing results which will safeguard the public and protect the profession. The number of such schools in the United States grows steadily smaller.

There is danger that the existence of a standard may force a formal rather than a real compliance with ideals. A premature effort to conform to an accepted standard may do positive harm. For example, there is reason to believe that in the case of medical schools in the South, where high school systems have had to be developed within a brief period, there has been an overstimulation of secondary and college education; that three-year high schools have changed to a four-year curriculum with little or no additional resources or increases in numbers and efficiency of teaching staff, and that colleges have offered courses which they are not prepared to give efficiently. Moreover, the "Class A" of the American Medical Association, having been accepted by state boards of medical examiners and thus become a part of the official machinery, has been extended in such a way as to produce serious anomalies. These will doubtless be largely removed as a result of the new survey which has recently been completed.

One of the ideals of modern medical teaching which needs constant emphasis is the provision of the best type of medical care for the sick. Laboratory and clinical methods must be thought of as a protection to the patient. Careful diagnosis, resourceful treatment, constant watchfulness are sources of safety and hope to those who come under the care of a modern university hospital. The prestige of the clinical teachers who are in charge is always at stake. The mutual scrutiny of members of the teaching staff, the alertness of students, together with unremitting search for new truth and its application to disease, make the teaching hospital the best place for the sick.

ESSENTIALS TO THE MAINTENANCE OF IDEALS

The widening conception of the physician as a social functionary, the enlarging theory of medicine as something which deals with the whole patient in his social environment, the demand for knowledge, insight and intelligent sympathy, the increasingly scientific nature of modern medicine call for a sound and broad training as a prerequisite for medical education. The demands made on the secondary schools and colleges are insistent and unrelenting. Attention has often been called to the serious situation which is created by this need of thorough preparation. Efforts must be made to improve and abbreviate the elementary and secondary

curriculum. Experts in the field of education are confident that time can be saved. By the frequent promotion of abler pupils, by the elimination of useless repetition, by concentration on fundamental things, by more intelligent methods of instruction it is reasonable to believe that two years could be saved and better results secured.

Medical education is so dependent on the general educational system that progress will necessarily be slow. This is especially true in the South. The Canadian plan for a six-year medical course so far as the better schools are concerned reflects a dissatisfaction with the preparation of students. It is to be hoped, however, that this policy will be temporary; for, as Dr. Colwell has clearly shown, there is great value in a nonmedical school preparation if this can be of the right sort.

Limitation of numbers is essential to the maintenance of ideals. There is a ratio between students and laboratory and clinical teaching facilities which cannot be safely ignored. The days of mass lectures are numbered. The constant use of microscope and culture tube by the individual student, the system of clinical clerkships, the reduction of bedside groups to a small number, the need of continual contact between teachers and students preclude the didactic, wholesale devices of earlier days. To admit a larger number of students than can be properly trained in accordance with scientific methods is vitally to impair the character of a school's work. It is a sacrifice of ideals. If it is desired to provide for larger classes, duplicate units of staff may be added and existing laboratory facilities more completely utilized. The corresponding duplication of hospitals, however, involves large additional costs.

In medical education the relation of the laboratory and the clinical years is organic. The antithesis which is often set up between these two aspects of medical education is most unfortunate. In the first and second years, the chief emphasis is laid on work in the laboratories; but this training ought to be extended right into the clinical phases of the curriculum. While it will usually happen that laboratory teachers will be graduates in medicine, many able laboratory men without the M.D. degree have demonstrated their capacity to develop cooperative and sympathetic team-work with clinical departments. The students in the laboratories should be frequently reminded of the bearing of their present work on their future responsibilities. The realization that the ideals of the laboratory are inseparable from rationalized clinical experience is equally essential. A few institutions are making systematic efforts to bring first and second year students in contact with dispensary and hospital problems, and into association with clinical teachers through occasional clinical lectures. The geographic separation of the laboratory work from that of the hospital and dispensary is a serious handicap to effective education.

In the clinical years it is essential to develop observation and reasoning power, to train students in the recognition of the early signs of disease. There is a certain value in the extravagant statements of a man like McKenzie who, in the stress he lays on the importance of contact with patients and of observational methods, seems to discredit the diagnostic resources of the laboratory. The dispensary as a means of educating students in the recognition of disease in its early stages needs greater emphasis. It is time to reconsider the whole problem of dispensary organization. Frag-

mentary periods of service by busy practitioners, hasty diagnosis, sometimes by clerks, are not consistent with the best interests of the clientele and do not provide satisfactory conditions of medical instruction. One of the pressing problems of medical education is found just here. Instructors must be paid and be asked to give a better type of service under more favorable conditions. The student needs to assume responsibility under supervision. It is important for him, in connection with social service, to make domiciliary visits, and to recognize the environment of the patient as an essential part of the problem of disease.

As to the hospital, it is recognized that effective teaching can be secured only in an institution which is under the complete control of the medical school. The devices of clinical clerkships, the individual responsibility of students, close relations between bedside and laboratory, the proper organization of the teaching staff, permanence of tenure, team-work, necropsy conferences, case conferences with physicians and social service workers, are all factors in the development of clinical training of the right type.

The ideals of clinical teaching involve one of the moot questions of contemporary medical education. The analogy of the development of laboratory leadership from the practitioner to the professional teacher is being applied to the problem of clinical instruction. Perhaps in the discussion of the "full-time" plan too much stress has been laid on the word "time." It might be better to use other terms as, for example, vocational and avocational teaching. That leadership in clinical teaching should be in the hands of men whose chief concern is the care of hospital and dispensary patients, the teaching of students, and the prosecution of research is struggling successfully for recognition. In other words, it is increasingly obvious that the vocational rather than avocational principle is to prevail in this field.

Illuminating experiments are being tried with reference to this ideal. Johns Hopkins, Yale, Washington University and the University of Chicago are committed to a trial of the idea of full-time in the sense that heads of the chief department and their immediate staff concentrate on their university duties. Other proposals call for chief concentration on hospital teaching, with some opportunity for incidental consultation practice. In still other cases, young resident physicians and surgeons will give their whole time to the organization and administration of hospital services and instruction, while the practitioner or avocational teachers carry responsibility for a large part of the teaching. This situation is in harmony with experimental, scientific methods. Under varying conditions the different plans will be given a test. The results will be watched with interest.

THE UNDERGRADUATE CURRICULUM

The question of differentiation in the undergraduate medical course is raised in one or two important ways. The curriculum is now so overcrowded that the proposal to introduce new subjects is naturally and justifiably resisted. There is now no room for specialties except in a superficial way. Specialization in the ordinary sense is quite impossible. Differentiation, however, for various forms of preventive medicine, e. g., public health administration, industrial hygiene and mental hygiene, seems feasible to some degree. Elective courses, especially in the fourth year, are being offered. It seems well to secure sufficient flexibility so

that men who have definitely chosen careers in some form of institutional or public health work may combine with their technical preparation a fundamental and sound course in medicine.

In spite of the overcrowding to which reference has been made, there is an increasing demand for the introduction in undergraduate teaching of such subjects as preventive medicine, psychiatry, institutional administration and some knowledge of social amelioration through clinics, popular education, improved housing, better food, recreation and the development of community responsibility. The introduction of medical sociology in the premedical course would be of distinct value. Something may be accomplished through lectures, conferences and visits included in the regular curriculum. Washington University Medical School is inaugurating a plan of this kind. The case conferences with social service workers in the Massachusetts General Hospital have already been mentioned. Dispensary experience has an important bearing on this subject. It is desirable that more and more emphasis should be laid on the medical practitioner's social responsibilities and on the changing standards and ideas of the times with respect to medicine and public health. Such a spirit or attitude, however, will be a relatively slow growth. Chief reliance must be placed on the daily influence of the teaching staff. Unless instructors are in sympathy with these newer developments, the mechanism of extra lectures and other devices will accomplish little.

The advancement of medical science will be a conscious purpose of the ideal medical school. Research in such an institution is not an incidental by-product or merely a means of stimulating teachers. It is a definite and persistent aim. It involves constant conference and planning and cooperation by all the departments concerned. Independent institutions for research cannot be expected to assume the entire responsibility in this field. Most of the workers for such institutions must be trained in the medical schools themselves. This responsibility for research calls for large expenditure for buildings, equipment, supplies and, above all, for a staff capable of making significant contributions to medical science. Only a few centers, in the nature of the case, will be in a position to perform this function of investigation in a systematic way. It is a mistake for institutions without adequate resources in men and materials to deflect to research time and energy which should be devoted to the undergraduate teaching. This is not to imply that many individuals even in such schools cannot or will not find some opportunity for investigative tasks.

GRADUATE MEDICAL STUDY

The crowding of the undergraduate curriculum, which has already been mentioned, means that specialist preparation must become the subject of graduate study. Postgraduate short courses have their value, but genuine graduate study can be carried on only where the best opportunities for laboratory training and clinical experience under the right sort of leadership are available. The University of Minnesota-Mayo Foundation experiment is showing promise. More than 130 graduate students are pursuing courses which lead to higher degrees on a university basis. In other institutions, similar movements are under way. As in the case of research, only a few institutions can be equipped and manned for offering genuine graduate instruction.

The proposed one-year courses for the specialties under the auspices of the New York Association for Medical Education suggest interesting possibilities. The clinical resources of a great city, and the presence of a large number of men recognized as specialists, offer an opportunity for the organization of teaching facilities. Success would seem to depend on the degree to which qualified teachers can give sufficient time to the work under satisfactory conditions of laboratory service and of access to controlled clinical material.

Continuation courses for practitioners represent a need in medical education which deserves careful consideration. Modern medicine insists that access to laboratory and hospital is essential to the maintenance and growth of professional power. Yet a great majority of physicians have no contact with these agencies. These practitioners are dependent on journals and on short courses for keeping abreast of professional progress. A relatively few take full advantage of these opportunities. There is pressing need of a widespread movement to enable physicians to continue their medical education. Before the war the American Medical Association offered a postgraduate course, a combination of correspondence instruction with group conferences. The Wisconsin University Extension Division is now maintaining a system of clinical instruction throughout the state. The possibilities of continuation courses in connection with diagnostic laboratories, rural hospitals and public health centers are obvious. There seems to be an opportunity for the development of a country-wide system of medical education for practitioners.

TWO GROUPS OF MEDICAL SCHOOLS

Judged by the criteria which are suggested in this paper, existing medical schools fitting the present need fall into two general groups:

1. *University Centers for Teaching and Investigation.*—The chief characteristics of these institutions are: broad and thorough preparation; limitation of numbers in proportion to facilities and staff; well-rounded laboratory equipment with professional teaching corps; complete control of adequate hospital and dispensary facilities with vocational leadership in the clinical departments, which include the chief specialties; practitioner or avocational clinical teachers organized systemically into a unified staff; geographic concentration of all phases of plant and instruction; laboratories and clinics in close relations of cooperation and interdependence; research a conscious purpose; facilities for graduate study.

2. *Training Centers, Parts of Academic Institutions.*—Two-year college requirement; limitation of numbers; fundamental laboratory facilities with professional teachers; control of appointments to hospital and dispensary staff; practitioner clinical teachers well organized in long service periods, assisted by full-time resident and other assistants; concentration of buildings and work; cooperation between laboratories and clinics; some opportunity for research by staff members.

ASSISTANCE TO MEDICAL EDUCATION

As to the policy of the General Education Board and the Rockefeller Foundation with regard to assistance to medical education, it may be said that there is no one, inflexible type of organization which it is proposed to suggest to all institutions. Aid has been given and will continue to be given to a few centers of the higher

type, but assistance is also being considered with respect to a number of institutions less highly developed. The General Education Board cooperates with medical schools in the United States, while to the Rockefeller Foundation falls the opportunity to work with medical centers in Canada and in other countries.

THE LARGER FUNCTION OF STATE UNIVERSITY MEDICAL SCHOOLS*

WALTER A. JESSUP, PH.D.

President, State University of Iowa

IOWA CITY

Within recent years there has come about a changed conception in regard to the responsibility of the general public for welfare policies such as public education; public improvements, standards of living, and health. Within the last century we have seen America develop a great public educational system in which the state has undertaken to make provision for the education of persons of types of ability ranging from the subnormal to the keenest student in the land. As the years have gone by, each decade has shown a markedly increased willingness on the part of the state to provide for new variations in the educational needs of the public, until at the present moment it is hard to find a state that has not only assumed large responsibility for the training provided in elementary schools, high schools and ordinary collegiate institutions, but also made provision for the training in technical fields—agriculture, engineering, commerce, law, medicine. In fact, an analysis of the development of state education confirms the prophecy that as the years go by the public, operating through the state, will ultimately respond to any well thought out demand on the part of educational leaders.

Paralleling this development in education has come an ever increasing conception of public responsibility for the care of certain cases of defectives, the insane, tuberculous and others. States have vied with each other in the organization and development of elaborate systems for the care of these unfortunates.

In recent years there has come a growing consciousness of the importance of the period of youth in a scheme of life such as ours: witness legislation for compulsory education, continuation schools, and regulation of the hours of child labor.

It is but a step farther for the state to interest itself in the health of children. It is obvious that neglect in the care of children means not only an enormous economic loss in the matter of self help and production, but also untold suffering in succeeding generations.

This interest in the health of children has been expressed locally by provision for medical inspection and school nursing. Perhaps Michigan is entitled to the distinction of being the first state to provide a state-wide hospital service for children needing attention. Iowa quickly followed, and later Oregon made similar provision.

LEGISLATION IN IOWA

Five years ago the general assembly of the state of Iowa enacted the Perkins law, which made provision for the surgical, medical and hospital care of all children in the state under 16 years of age whose parents

* Read before the Annual Congress on Medical Education and Licensure, Chicago, March 1, 1920.

were unable to meet the expense involved. Four years later, further legislation was enacted extending this type of service to indigent adults, so that at present the state of Iowa makes provision for the surgical, medical and hospital care in all cases which are considered remediable. This service is provided through the State University of Iowa College of Medicine, and includes service given in a dozen different departments. Thousands of patients have taken advantage of this provision. There has been a steady stream of deformed and suffering humanity pouring into Iowa City week in and week out since the first enactment of the law. Practically all of the infantile paralysis patients of the state have come to this hospital as either indigent or pay cases. The demand for orthopedic service has been so large that the state has undertaken the task of manufacturing her own braces and casts. The speech defect cases have been so numerous as to necessitate a special school for training in speech after remedial operations have been performed. Special diet, laboratory facilities have been provided in connection with the infant feeding cases.

No service undertaken so far by the state in connection with any of its institutions has received greater approval on the part of the public. After two years of experience with this service to the children, the state was asked to provide a children's hospital to care for the cases. Despite the fact that this appropriation was sought during the war, there was not an opposing vote registered in either branch of the legislature. Two years later, when the proposal was made to extend these provisions to adults, there was not a single vote in opposition. In other words, since inaugurating the service five years ago, the two general assemblies have expressed direct approval of the service rendered without an opposing vote—a remarkable record.

For many years the College of Medicine has been rendering special service to the wards of the state in the institutions for defectives. Hundreds of patients come each year from the state orphanage, and schools for the blind and deaf. The regular clinical service for which a charge is made has likewise attracted thousands from every part of the state.

Thus, with the addition of the indigent cases it can be seen that the hospital has really become a state hospital in every sense of the word. People in the most remote sections of the state think of this service constantly in connection with the problem of caring for children and adults who need remedial care.

The commitment laws have been drawn so as to provide for the cost not only of the remedial care but also for transportation of the patient, including the expense of a caretaker of the patient, when needed. The university makes its financial adjustment with the state authorities, thus simplifying the problem of collection on the part of the hospital. The conditions of commitment are made so simple and direct that there is the minimum of difficulty in getting patients into the service, as will be seen from a study of the first two sections of the law:

SECTION 1.—General Provisions for Free Hospital Service.—Whenever it shall appear to any physician, county supervisor, township trustee, public health nurse, overseer of the poor, policeman, priest or minister that there is any legal resident of his or her county over 16 years of age afflicted with any malady or deformity which can probably be remedied by proper care and medical or surgical treatment, if said person, or the parent, parents or guardian or other person having legal custody of said person, as the case may be, is unable financially to provide proper care and medical or surgical

treatment, it shall be the duty of such physician, county supervisor, township trustee, public health nurse, overseer of the poor, policeman, priest or minister to report the same to the judge of the district or superior court having jurisdiction in the county in which said person resides.

On the filing of such report with the judge of the district court or superior court as aforesaid he shall appoint some physician who shall personally examine said person with respect to the malady or deformity. Such physician shall make a written report to said judge, giving such history of the case as will be likely to aid the medical or surgical treatment of such deformity or malady, and describing the same, all in detail, and state whether or not, in his opinion, the same can probably be remedied. Such report shall be made within such time as may be fixed by the court and on blanks furnished as hereinafter provided. It shall also be the duty of said judge to have a thorough investigation made by the county attorney of his county regarding the financial condition of the said person, or of the parent or parents, guardian or other person having legal custody of said person, as the case may be.

SECTION 2.—Procedure for Admission to Hospital.—On the filing of such report or reports, said judge of the district or superior court, as aforesaid, shall fix a date for the hearing on the complaint and shall cause the person, or the parent or parents, guardian or other person having legal custody of said person, as the case may be, to be served with a notice of the hearing and he shall also notify the county attorney who shall appear and conduct the proceedings; and on such complaint, evidence may be introduced. If the judge finds that the said person is suffering from a deformity or malady which can probably be remedied by medical or surgical treatment or hospital care, and that the person, or the parent or parents, guardian or other persons having legal custody of said person, as the case may be, is unable to pay the expenses thereof, said judge may, with the consent of the said person, or parent or parents, guardian or other person having legal custody of said person, as the case may be, enter an order directing that the said person shall be taken to the hospital of the college of medicine of the state university of Iowa at Iowa City for proper hospital care and medical or surgical treatment; the expense of such hospital care and treatment to be met in the manner hereinafter provided.

Provided, that no such person shall be received into said hospital of the college of medicine of the state university of Iowa for care and treatment, unless, in the judgment of the admitting physician, there shall be a reasonable probability of such person's being benefited by such hospital care and medical or surgical treatment.

Emergency service is provided without waiting for the carrying out of this procedure.

Complete service is provided, including roentgen ray or radium, laboratory examinations, braces and even schooling for those of school age, and the best diagnostic and remedial care. The cost of everything exclusive of the salary of the staff is paid by the state on thirty-day settlements based on the number of patient-days.

The demands on the hospital have been growing steadily for many years. With the influx of more state patients it has been necessary to increase hospital facilities from 450 to 600 beds. The number of annual admissions is now around 15,000.

A few years ago the state board of health centered its laboratory work in the laboratories of the College of Medicine. The state epidemiologist is also a member of the staff of the College of Medicine. A public health nursing course has been authorized. The extension service in the field of follow-up work in the case of Perkins law children who have been treated in the university is proving to be one of the best forms of social welfare work. A part of the university's education program includes the distribution of thousands of bulletins on the feeding of schoolchildren, the care of infants, and the like.

In line with the general policy of coordinating the state wide service, the state has just authorized the creation of a psychopathic department at the university with a special hospital and adequate support for research work in this field.

This enlarged consciousness on the part of the public as to its responsibility in regard to health is by no means confined to a few states. Indeed, steps are being taken to secure the leadership of the federal government in assuming this responsibility. There is little doubt that within the next decade health service under some such general plan as outlined above will be provided almost everywhere. The states will have to determine whether or not they wish to establish this service in isolated hospitals as has been done in the past in the case of sanatoriums for the tuberculous, hospitals for the insane and the like, or whether they wish to coordinate this work with that of the training of physicians in the college of medicine.

While it is true that in some schools the supply of clinical material is so large that these patients would be of little value in connection with the training of physicians, yet in many states it would be disastrous from the standpoint of the teaching clinic for the state to establish such a hospital apart from the college of medicine, necessitating, as it would, constant duplication of the staffs of the two institutions. The waste would be calamitous. The experience in Iowa is such as to suggest that this type of work can most successfully be done in connection with the college of medicine.

CONCLUSIONS

Our experience leads to these conclusions:

1. In view of the great rapidity with which the demands on our staff and hospital have grown, it seems to us important to note that any state in attempting to provide this type of service should make very comprehensive plans on the material side, which should include liberal provision in space and staff not only for adequate service to the indigents but also for adequate provision for the ever growing number of pay patients.

2. It is very important that future plans include ample provision for the vigorous prosecution of medical research. Otherwise the teaching staff may easily be overwhelmed with routine, with a consequent slump in growth. Furthermore, the unusual clinical demands serve as a constant challenge to the student of medicine.

3. Since the success of the work is absolutely dependent on skill and devotion of the staff, it is essential that many adjustments in the conditions of teaching must be made. The problem of full-time teaching becomes more acute.

Satisfactory adjustments of these problems must be worked out if medical teaching is to be kept at the highest standard.

Other departments in the field of technical education have had to meet the same situation. Indeed, in the field of agricultural education a very large part of the function has been the providing of service for the public. So much is this true that it would be hard to conceive at the present moment of a college of agriculture without its elaborate organization in the direction of special agricultural service to the state. Within the next few years we may expect in many state universities just such close coordination in the problems of the training of physicians, furthering research that will contribute to the knowledge of the field and extending health service to the public.

To the degree that the colleges of medicine of the state universities are alert to these new demands and effective in their responses will these colleges become real leaders in this present movement looking toward the highest type of physical and mental efficiency.

CHANGES IN THE BLOOD IN INFLUENZA *

RALPH A. KINSELLA, M.D.

AND

GORONWY O. BROWN, M.D.

ST. LOUIS

The tendency to nosebleed, the bloody sputum and the hemorrhagic character of the lesion in the lung, in an uncomplicated case of epidemic influenza, give rise to the inference that there are changes in the blood in this disease which predispose to hemorrhage.

TABLE 1.—EFFECT OF SODIUM CITRATE ON CLOTTING
TIME OF THE BLOOD

11844	2/20/20	14½	99.4	Before receiving citrate
11844	2/20/20	6¾	½ hour after receiving 1 gm. of sodium citrate intravenously

It was for the purpose of inquiring into this point that the present study was undertaken, and this report is a preliminary summary of the results that were obtained.

The special features studied were the clotting time, the platelet count, the fragility of the red cells, and the number of leukocytes.

METHODS

For studying the clotting time, blood was drawn from the median vein into a syringe wet with physiologic sodium chlorid solution, and 1 c.c. was immediately inserted in tubes 1 cm. in diameter also wet with physiologic sodium chlorid solution. It was found that if the syringe was one of small capacity and the quantity of blood drawn only a little more than that necessary for the test, the clotting time was much shorter than if a large syringe was used and the quantity of blood drawn was several cubic centimeters more than necessary for the test. The cases in Table 3 were studied by the latter method. Care was taken to use exactly the same technic for test cases and the normal controls.

* From the Medical Clinic, City Hospital, St. Louis University School of Medicine.

For counting the platelets, the technic described by Wright and Kinnicutt¹ was used. Counts of normal individuals were made as controls.

For estimating the fragility of red cells, the method described by Hill² was employed.

* The two readings of Patient 11795 were taken twenty-four hours apart, and after the first test, 1 gm. of sodium citrate was given as was done in each of the other cases.

RESULTS

Clotting Time.—Forty patients were studied. In all, the diagnosis of influenza was clear from the clinical manifestations. All occurred during the height of the epidemic. Some were in the second or third day of convalescence. The majority were studied between the third and sixth day of disease. The normal clotting time with the method used was definitely shorter than that of the patients. There seemed no relationship between degree of delay and severity of disease. Moreover, the delay was present even when secondary infections with pneumococci or hemolytic streptococci had occurred. It was as though the delay in clotting time represented an influence essentially associated with the intoxication of influenza, which persisted throughout the secondary pneumonia, and into convalescence.

Platelets.—The results are shown in Table 3. Counts were made in twenty-one cases. The reduction in the majority of the cases is very definite. As in the case of clotting time, the reduction of platelets was independent of the stage of the disease or of the presence of secondary infections. The reduction of platelets and the delay in clotting time occurred hand in hand. Both were apparently independent of the number of leukocytes present, as shown by Table 3.

Leukocytes.—In general, it may be said that influenza is attended by an absence of leukocytosis, often

extending to a degree of leukopenia. The presence of leukocytosis is good evidence of the presence of secondary infection.

COMMENT

As pointed out by Weil,³ intravenous injection of sodium citrate hastens clotting, although in the test tube the same salt in sufficient concentration will prevent clotting. Similar action is ascribed by Addis⁴ to sodium phosphate. To determine whether the same response to sodium citrate could be obtained in patients with influenza, possibly affecting the condition thereby, five patients were studied as shown in Table 1. The effect of intravenous injection was prompt. In one case (11278), the character of the sputum markedly changed from one of bloody appearance to one almost free from blood. It was thought, in the beginning, that patients improved after such treatment; but further tests made such a conclusion doubtful. In patients with streptococcus empyema, a peculiar reaction usually followed the injection of citrate, which consisted in a sudden, though transitory, gasping for breath. In the test tube, the addition of sodium citrate seems to inhibit the hemolytic action of serum of such patients on a suspension of sheep red blood corpuscles. Accordingly, the explanation of this clinical reaction was not found.

In seeking an explanation for the peculiar effect of sodium citrate on clotting time in vivo, it was thought that the salt might rapidly diffuse after entering the

blood stream and be diluted so that only a minute amount remained after a few minutes, and that such a minute quantity might enhance the condition of "thrombin" and "prothrombin." Accordingly, tests were made of four patients and two normal controls, in which minute amounts of citrate in vitro seemed to have the effect of shortening clotting time, while the usual concentration of 0.2 per cent. prevented clotting. Further investigation must be made to substantiate this finding, shown in Table 2.

SUMMARY

The clotting time of the blood of patients with influenza is delayed.

The number of platelets is reduced in such patients.

Neither of the foregoing conditions changes with the onset of secondary infection, although the number of leukocytes is usually greatly increased in secondary infection.

The fragility of the red cells is probably increased in influenza.

CAN THE TUBERCULOSIS TRANSMISSION RATE BE REDUCED?

JAMES G. CUMMING, M.D. (ANN ARBOR, MICH.)

Lieutenant-Colonel, M. C., U. S. Army

A. E. F., VLADIVOSTOK, SIBERIA

What are the possible avenues of tuberculosis transmission among individuals? Is it direct contact by the air route, though spray that is expelled by an act of coughing, or through dried sputum in public places? In answer to this question it may be said, that if the results of investigations of the influenza-pneumonia epidemic can be taken as a key to sputum-borne disease transmission, the transmission rate resultant from the distribution of tuberculosis by the air route among adults is of minor importance.¹ In the infant, however, another link may be added to this avenue of transmission: that of soiling the hands on a contaminated floor.

In contrast to direct contact, transmission may take place through several common routes by indirect contact: (a) through hand-to-mouth infection, the hands being soiled by contaminated inanimate objects, and (b) through inanimate object-to-mouth infection, the objects entering the mouth of the tuberculous as well as that of the nontuberculous. There are other ramifications in the routes of travel, but for the purpose of this paper the foregoing are the most important.

Here it might be said that our efforts to control the disease by the restriction of spitting and coughing have not given results that inspire a high degree of confidence. Should it be assumed that public spitting is a large factor in transmission, it is to be pointed out that this restrictive measure is of limited value because it is an attempt to deal with the individual. In this disease, as in all communicable diseases, a successful attack cannot be made through the individual—the animate—but must be made through the inanimate; or, as in insect-borne diseases, through insect destruction. It might be laid down as fundamental, from an epidemiologic standpoint, that the final solution in the eradication of any disease depends not on the control of the animate, but on the control of the inanimate through universal mass action.

On this basis there would be some encouragement in a plan of attack which could be universally applied to the most common *saliva*-contaminated inanimate objects. If this could be accomplished, the major avenue of transmission would be closed, the transmission rate would be immediately diminished, and on the basis of "the theory of case and source elimination" the majority of the tuberculous cases of the next human cycle of this organism would be eliminated as sources of infection. Likewise, by continuing this

blocking in subsequent cycles of the organism, the majority of cases and sources would be eliminated. Thus, it is only by application of this principle through its cumulative action that the disease will be ultimately eradicated.

What is the most common inanimate object which becomes sputum contaminated by one person and then, without being rendered aseptic, enters the mouth of another where the saliva and its organisms are deposited? The donor of the saliva may be tuberculous and the recipient nontuberculous. This exchange of inanimate objects with their attached organisms takes place three times a day between tuberculous and nontuberculous persons. These objects are eating utensils. Objection might be made to the possibility of any such transfer of tubercle bacilli, on the assumption that only the sputum contains large numbers of organisms, while the saliva of the oral cavity is comparatively free from contamination by this organism; also that eating utensils are washed, and furthermore that such utensils when used by the tuberculous, who have had hospital training, are boiled.

The saliva in the open case contains many tubercle bacilli; dishes when washed only in warm water are not rendered aseptic—the average removal of organisms is about 70 per cent.;² and the tuberculous who have had the advantages of training in a sanatorium are in the minority.

TRANSMISSION EXPERIMENTS

The field and laboratory investigations on the transmission of measles-pneumonia at San Antonio, as well as those on influenza-pneumonia at the port of embarkation, Newport News, Va., and in public institutions presented a lead as to the most likely major avenue of tuberculosis transmission.³ From these investigations it was deduced that direct contact through the air route played at best only a minor rôle in sputum-borne transmission, while indirect contact through hands and eating utensils was the major avenue of distribution.

The plan of the work was: (1) to determine the presence or absence of tubercle bacilli on eating utensils after they were used by tuberculous patients; (2) to determine the presence or absence of these organisms on eating utensils after these utensils were washed by the usual hand method in hot water; (3) to determine their presence on the hands of patients, and (4) to determine their presence in the air of tuberculosis wards.

In carrying out these researches it was recognized, from the standpoint of tuberculosis transmission, that of all eating utensils, the spoon would be the most likely transmitting object. This is because the spoon actually enters the mouth; the fork does, too, but of the two the spoon has the larger surface area to which mouth organisms may adhere. The spoon was, therefore, chosen as the transmitting agent in these experiments.

Spoon Wash Water.—In the first group of experiments, which were undertaken, May 1, 1919, the spoons used in two open cases of tuberculosis were washed after each meal with a cloth in 150 c.c. of hot water. About 50 c.c. of this wash water were centrifugated, and the centrifugate of eleven of these specimens was

2. Observations as yet unpublished.

3. Lynch, Charles, and Cumming, J. G.: The Distribution of Influenza by Indirect Contact—Hands and Eating Utensils, *Am. J. Pub. Health* 9: 25 (Jan.) 1919.

1. Cumming, J. G., and Spruit, C. B.: Transmission of the Pneumonia Group of Organisms, to be published.

injected subcutaneously into guinea-pigs. Of these eleven guinea-pigs, three died from generalized tuberculosis.

In the next group of experiments the procedure was the same except that a single spoon was used instead of two as in the previous experiments. Among twenty guinea-pigs so inoculated, eight died from tuberculosis. Of the thirty-one injected animals in this group, eleven, or 35 per cent., died from tuberculous infection.

Spoon Rinse Water.—In these experiments, spoons were first washed by hand in hot water. They were then placed in a large mouth bottle containing 50 c.c. of hot water and shaken for five minutes. This rinse water was then centrifugated and the centrifugate injected. Twelve guinea-pigs were injected with the pooled rinse water centrifugate from the spoons used in two cases of open tuberculosis. The same two patients were rarely used in successive experiments. Of the twelve animals so injected, three died from tuberculosis. Of twenty-four guinea-pigs injected with the rinse waters from single spoons, six died from tuberculosis.

Of the thirty-six injected animals in this group of experiments, nine, or 25 per cent., died from tuberculous infection.

Hand Scrapings.—The hand scrapings from tuberculous patients were obtained by first soaking the

the wash water injections. It is believed that the hand washing of the spoons in this series of experiments can be taken as representative of the usual method of washing eating utensils. If this is so, the difference in the percentage of deaths between the animals injected with washings and rinsings indicates that only about 30 per cent. of the spoons used by tuberculous patients are rendered free from the organism by the usual hand method of washing.

This group of rinse water injections, with its 25 per cent. mortality, demonstrates the facility of tuberculosis transmission and indicates that in families the eating utensil is the *major* avenue of distribution.

Imagine a family of six in which there is one open case of tuberculosis. What are the chances of introducing tubercle bacilli from the patient in this open case through the spoon route into the mouths of the remaining five members of the family? I do not wish to convey the idea that only the spoon is responsible for transmission; but among all eating utensils, it is the chief conveyer. Since there are six persons in the family, the chances are five to one that at each meal the contaminated spoon is used by one of the well members of the family. But there are three meals a day, and of all eating utensils there are three which actually come in contact with the mouth or lips: the spoon, fork, and cup. As there are three contaminated conveyers, three meals a day, and six persons in the family, the chances are that each well person during the day uses approximately two conveyers contaminated by the tuberculous person. These chances of exchange increase with a decrease and decrease with an increase in the number composing the family.

In view of this exchange of eating utensils in a family group, and in view of the fact that the majority of eating utensils are hand washed, by which method they are neither freed from all organisms nor rendered aseptic, and in addition, that the eating utensil is the most common inanimate object which enters the mouth of the tuberculous as well as that of the nontuberculous, is it not obvious that the eating utensil is the major avenue of tuberculosis transmission?

The primary infection, then, is not the result of airborne transmission, nor is it in the lung as is generally maintained; but it is saliva-borne and in lymphoid tissue. The primary focus might be either in the tonsil or in a mesenteric lymph node. From these primary foci, tubercle bacilli are subsequently passed into the lymph channels and thence to the blood stream. Since the first network of small vessels through which the blood passes is in the lung, the organisms are filtered out, just as in hookworm infection, and here their multiplication produces a secondary focus. In the lung, the evidence indicates that extension again takes place through lymph channels, resulting in multiple foci. From an epidemiologic standpoint the breaking down of these multiple foci, the liberation of tubercle bacilli, the contamination of saliva, the soiling of eating utensils by saliva, and the use of these without being rendered aseptic by boiling water, results in the introduction of repeated small doses, one or more of which are finally carried through the barrier and involve lymphoid tissue of the newly infected person; thus there is completed the cycle of transmission. It is not the large dose of tubercle bacilli that is usually responsible for infection, but it is the repeated small doses.

Although the hand scraping injections gave the highest mortality among the several groups of injected

RESULTS OF INJECTIONS IN GUINEA-PIGS

Air washing.....	11	1	0	0

hands in warm water for a few minutes and then scraping off the epithelium with a scalpel. Of seven animals injected with the scrapings so collected, three, or 43 per cent., died from tuberculosis.

Air Washings.—The specimens of air dust were obtained by drawing air through water by means of a suction pump. The inlet was 3 feet from the floor, the washing process was in each test continued throughout a twenty-four hour period, and there was a total of 17,280 liters of air washed. About 50 c.c. of the 150 c.c. of water used for each twenty-four hour run were centrifugated, and the deposits of eleven of these specimens were injected into guinea-pigs. During an observation period of nine weeks, only one of the injected animals had died; its death, however, was not due to tuberculosis.

COMMENT

Since tuberculous sputum passes through the oral cavity on its way from the lungs of the tuberculous to the exterior, this cavity becomes contaminated. Objects that enter the mouths of these patients become contaminated with the specific organism. As eating utensils are the most frequent inanimate objects which come in contact with the mouth, it is to be expected that guinea-pigs injected with the wash water from eating utensils of the tuberculous patient would die from tuberculosis. It will be noted that 35 per cent. of animals so injected died from the infection.

But the outstanding feature of this series of experiments is that the percentage of deaths, 25, from the rinse water injections was almost as great as that from

animals, it is not to be concluded from this result that the hand-to-mouth route of travel is the most frequent mode of tuberculosis transmission. The hands of the tuberculous are contaminated with tubercle bacilli, but our hands only handle objects in common with those of others, and do not enter the mouths of other persons as do eating utensils. The hands are dry, which makes transfer to objects difficult. In addition there is a five-link chain in hand-to-mouth transmission, while through eating utensils there is only a three-link chain, and the two end links are moistened by the saliva which makes for facility of transmission. From a general consideration of tuberculosis transmission it appears that hand-to-mouth spread is second in importance to eating utensil distribution.

None of the animals injected from air washings died from tuberculosis, and although these animals were under observation for only nine weeks there were no indications of infection—no nodules at the point of injection. This result, in conjunction with our reports of former research¹ on the air dust of streptococcus wards, where it was found that hemolytic streptococci were practically never found, might well lead one to conclude that the air route of travel of the tubercle bacillus, as well as that of the hemolytic streptococcus, is a remote possibility. It might be well to consider that there is an exception to this in the creeping infant. In this case, the first link in the chain is from the adult through the air, directly to the floor, and thence to the infant by the hand-to-mouth route. But this is indirect contact and not direct contact transmission, nor is it the major avenue of distribution among persons.

It might be well to add here that there is no disease which man will not be able to control; and so long as he regards any disease or group of diseases as transmitted by the air route, successful control is impossible. In general, we have little or no control over the air that we breathe; consequently we have little or no control over this as a transmitting avenue. This is not so in the case of inanimate objects, through which the major avenue of transmission can be readily closed.

The findings here presented in no way influence the teaching that promiscuous spitting and careless coughing should be heartily discouraged, not only from the standpoint of common decency, but also from that of disease prevention.

CONCLUSIONS

1. The attack against tuberculosis has not resulted in a marked reduction in the transmission rate, because this attack has been made chiefly against the minor avenues of distribution.
2. A communicable disease can be successfully controlled and eventually eradicated only by an attack against the major avenue of spread.
3. The group of rinse water transmission experiments here presented gives a high mortality from tuberculosis and affords striking evidence of the importance of indirect contact transmission in this disease.
4. The results of the rinse water experiments, in conjunction with epidemiologic information, indicate that the major avenue of tuberculosis transmission is through eating utensils.
5. Eating utensil transmission is a three-link chain; the two end links are moist, and this makes for facility of transmission.
6. On the basis of "the theory of case and source elimination," by making the attack through the major

avenue of transmission, tuberculosis is as controllable as is typhoid fever.

7. It should not be assumed that we should learn to live with tuberculosis, but rather that we should learn how to reduce the transmission rate.

8. Just as a 99 per cent. removal of organisms from a polluted water supply controlled the intestine-borne infections, so, likewise, will a similar reduction of organisms on eating utensils control the saliva-borne infections.

9. The universal application of the principle of eating utensil asepsis will accomplish more in the control of tuberculosis than will any other single measure of practical application.

10. In the control of tuberculosis, the adoption of the principle of using boiling water as a cleansing and a pasteurizing agent of eating utensils applies especially to the small messing group—the family—and also, but to a less extent, to the public eating place.

TYPHOID FEVER IN THE AMERICAN EXPEDITIONARY FORCES

A CLINICAL STUDY OF THREE HUNDRED AND SEVENTY-THREE CASES *

VICTOR CLARENCE VAUGHAN, JR., M.D.†

Major, M. C., U. S. Army

DETROIT

This clinical study of typhoid fever as it occurred in France among the troops of the American Expeditionary Forces has been made under the direction of Col. J. F. Siler, chief of the Division of Laboratories and Infectious Diseases, Office of the Chief Surgeon, A. E. F. It is based on a personal investigation of the cases of typhoid fever, of paratyphoid, and of clinical typhoid as they occurred in the various army hospitals, supplemented by a statistical study of detailed reports on 373 cases.

As a result of the system employed at the ports of embarkation in the United States, nearly all soldiers leaving for France received preventive typhoid inoculations prior to leaving this country. A study of this disease as it occurred in France becomes, then, a study of typhoid fever in the "immunized" individual. The aim of this investigation has therefore been to determine the clinical difference, if any, between typhoid fever in the vaccinated and in the nonvaccinated, and the effect of vaccination on the course of the disease as well as on the severity and the mortality. Investigations from the point of view of laboratory work and epidemiology have been touched on only as they affect the clinical aspects of the disease.

INCIDENCE

Chart 1, prepared from weekly reports of the sick and wounded to the Surgeon General's Office, shows that the typhoid group of diseases had been present in isolated cases since the autumn of 1917. The rise in the curve for November, 1917, while nearly as high as for that of December, 1918, must not be understood to indicate as great a number of cases. Showing, as it does, the annual death rate per thousand for each week, the curve for November, 1917, is based on a very much smaller total number of men in the American

* Because of its length, this article is published in two parts. The second part will appear next week.

† Dr. Vaughan died, June 4, 1919, at St. Aignan-sur-Cher, France.

Expeditionary Forces than for the fall of 1918. The pronounced rise in the curve for August, 1918, was due in great part to disease at the front. With the men in action and forced at times to drink from polluted streams and rivers, to drink even from the water lying stagnant in the shell holes, it is but natural that the incidence of enteric diseases should take an upward jump. The effect of this is shown in the curve for dysentery in the same chart.

Chart 1.—Morbidity among troops in expeditionary forces during 1917-1918; annual rate per thousand: solid line, typhoid and paratyphoid; broken line, dysentery.

Since the armistice there have been two or three small epidemics of typhoid fever. In December, 1918, there was a rise in the incidence of the disease in the Seventy-Seventh and Seventy-Ninth Divisions which continued for more than three months. Investigation showed that in the Seventy-Ninth Division typhoid infection had occurred while the troops were in action in the Argonne, since which time it had been endemic, the source of infection being apparently healthy or convalescent carriers.¹ We had no opportunity in connection with our studies of investigating the infection in the Seventy-Seventh Division, but presumably the etiology was the same.

In March, 1919, a small outbreak occurred among the troops stationed in the vicinity of Marseilles. Here the disease originated from two sources: (1) polluted water at times improperly chlorinated, and (2) carriers and typhoid cases passing through the camp, especially from combat troops and other organizations previously stationed in infected areas in the former zone of the advance.

Cases providing material for this paper date from Jan. 1, 1919.

TYPHOID FEVER

This paper will be divided into a consideration of straight typhoid fever and of the two paratyphoids, A and B, and of so-called clinical typhoid fever, a condition in which the clinical findings were quite characteristic of the disease but in which the causative organism was not isolated. No case has been accepted for our statistical study as being undoubted typhoid or paratyphoid fever unless the causative organism has been isolated either from the urine or feces or preferably from the blood. I recognize that the finding of the typhoid or a paratyphoid bacillus in the feces alone does not establish a diagnosis, but have assumed that this finding, together with the presence of characteristic clinical symptoms of the disease, and with negative blood cultures, form sufficient evidence on which to base a diagnosis.

The clinical and laboratory findings in 270 cases infected with *Bacillus typhosus* form the basis for this portion of our report.

1. Vaughan, V. C., Jr.: Report on Typhoid Fever in the Seventy-Ninth Division.

Blood Cultures.—In summarizing the results of the blood examinations, I here include for convenience the results in the paratyphoid cases. Of 331 cases studied with a view to isolating the causative organism, blood cultures were made in 274. In the remaining fifty-seven, no blood cultures were made, but diagnosis rested on the isolation of *B. typhosus* or *paratyphosus* from the stool or urine. Of these 274 cases, 180 were positive and ninety-four negative for the organisms in question. These results, representing cultures taken at all stages of the disease, show that the organism was isolated from the blood in 65.7 per cent. of cases of true typhoid and paratyphoid fevers (Chart 2).

Table 1 gives the actual number of cultures taken in each case. The fact that in one case of proved typhoid six blood cultures were negative illustrates the value at times of taking cultures of the excreta.

In Chart 3, which gives the actual number of positive and negative blood cultures on successive days of the disease, the greatest number of positive cultures is recorded between the tenth and the fourteenth days of the disease. This is because the greatest number of cultures were also taken during that period. At the end of the first week of the disease and at the time when rose spots were appearing and the spleen was becoming palpable, typhoid was suspected and blood cultures

were first made. The average date of diagnosis was the eleventh day of the disease. Chart 4 gives the same information as that given in Chart 3, on a percentage basis. It shows that during the first week of typhoid fever the organism was isolated from the blood in 65.7 per cent. of trials, and during the second week in 54.7 per cent. During the third and fourth

weeks, blood cultures were positive, but in diminished frequency. (Relapses shown in Chart 3 are not included in Chart 4. It is possible that some of the other positive blood cultures obtained late (Chart 4) were also in relapse, although not reported as such.)

Urine and Feces.—Of 109 cases in which urine cultures were made, thirty-seven, or 33.9 per cent., gave positive results. Of 270 in which cultures of the stools were taken, 193, or 70.2 per cent., were positive for *B. typhosus* or one of the paratyphoid organisms (see

Chart 2). In Chart 5 it is seen that urine cultures were most frequently positive during the second and third weeks of the disease, and that stool cultures were positive in as high as 57 per cent. of cases in the first week, from which high point the percentage gradually

typhoid B bacillus to be agglutinated in much higher dilutions than *B. typhosus* and particularly than the paratyphoid A bacillus, together with the presence of group agglutinins or coagglutinins, further tends to vitiate the results. Antibody titration by the Dreyer method promises better results in the vaccinated, but time and equipment did not permit its use in this clinical study.

SYMPTOMATOLOGY

Antityphoid inoculation as an auxiliary to sanitary measures has diminished the occurrence of typhoid fever but has not freed us entirely from the disease. In the United States Army in 1914, two years after vaccination had been made compulsory, there occurred 7.5 cases per hundred thousand. Vaccination confers only a relative immunity, and in France, where the sanitary conditions could not always be ideal, we had expected a moderate increase in the number of cases.

We had been led, however, to expect that the clinical condition encountered in the inoculated would be quite different from that in the nonvaccinated. Gay,³ in quoting foreign workers, remarks that the mortality among the vaccinated, as compared with the nonvaccinated, decreases even more rapidly than does the morbidity. He says: "Not only is the mortality rate decreased, but the disease itself is found to undergo a very distinct modification when it does occur in the vaccinated. It has frequently been found to be so mild as to offer great difficulty in its classification."

We have analyzed the clinical symptomatology in 270 cases of proved typhoid fever, in all of which the patients had been vaccinated previously. The result of our analyses are given in Chart 7, on which are shown the incidence and average day of appearance of the symptoms and the more frequent complications. The ordinates represent the total percentage of cases in which any one symptom was observed, while the abscissas indicate the average day of the disease on which each symptom was noted. Thus, one may read that diarrhea occurred in 45 per cent. of the cases and that the average day of appearance was the fourth day; or that rose spots were noted in 62 per cent. of the cases, usually first recognized on the twelfth day. From this chart, then, the entire clinical symptomatology may be reconstructed.

The most striking feature of the disease in the inoculated, as here graphically shown, is its almost classical resemblance to the old typhoid as we knew it in the unvaccinated. The chill in nearly one fourth, the early bronchitis in well up toward one half, the initial constipation in about one fifth of the cases, followed in a few days by diarrhea in one half, meteorism, rose

Chart 3.—Actual number of positive and negative blood cultures in proved cases of typhoid and paratyphoid by days after onset of disease.

decreased so that by the sixth week they were positive in only 9 per cent. Figures for later weeks both in the urine and the feces curves, are based on smaller numbers of cultures and are therefore less reliable.

Simultaneous blood and feces cultures made in 150 instances in successive weeks of the disease (Chart 6) showed that during the first week the likelihood of making positive diagnosis by stool culture was two thirds as great as by blood culture, whereas in the second week the chances were about even, the advantage still resting slightly with the blood method. During the third week the opportunities for obtaining the organism were somewhat better by the stool examination. After the third week the possibility of obtaining the organism decreased by both methods, the stool method remaining the better. In fifty out of the 150 cases, urine cultures were also made. Perhaps the most important fact to be brought out in this analysis is the persistence of positive blood cultures into the third week in a certain proportion of cases.

Chart 4.—Percentage of positive blood cultures in cases of proved typhoid and paratyphoid by days after onset of disease.

Serodiagnosis.—Serodiagnosis, particularly by the use of the Widal reaction, has not been relied on in the diagnosis of these infections. In individuals inoculated with the triple vaccine the Widal as usually performed is valueless.² The well known tendency of the para-

Chart 5.—Above, percentage of positive urine, cultures in successive weeks of the disease in 109 cases of proved typhoid; below, percentage of positive feces cultures in successive weeks of the disease in 270 cases of proved typhoid.

2. Rist, E.: J. Lab. & Clin. Med. 3:1 (Oct.) 1917.

3. Gay, F. P.: Typhoid Fever Considered as a Problem of Scientific Medicine, New York, the Macmillan Company, 1918.

spots and enlarged spleen in the second week, complications in the third week, and cessation of the fever averaging around the end of the fourth, form a clinical picture in no wise differing from that of typhoid in pre-vaccination days.

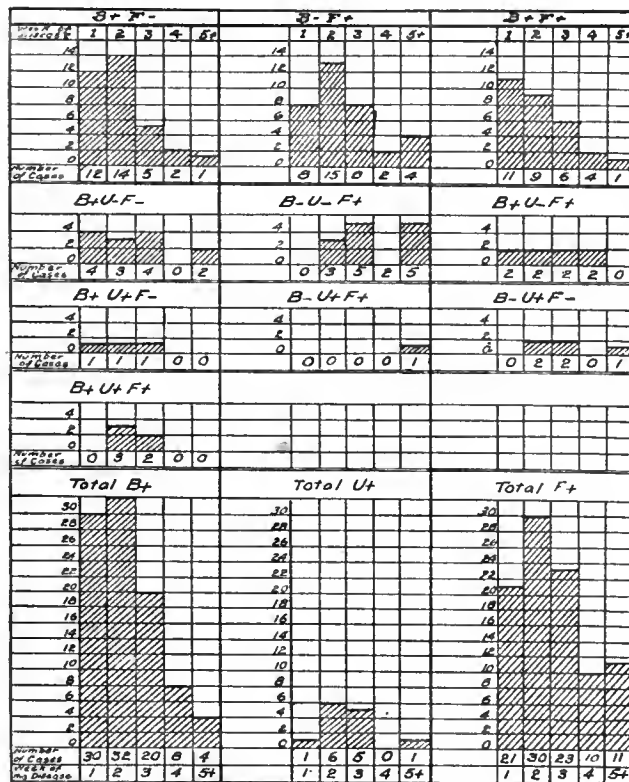

Chart 6.—Comparison of simultaneous blood, urine and feces cultural results, by weeks of disease, in 150 cases of proved typhoid.

Not only was this resemblance true on paper, but it was likewise true at the bedside. In the majority of the cases in which the typhoid bacillus was isolated there was no difficulty in the clinical diagnosis. Typhoid facies, coated tongue, rose spots, palpable spleen, rigid, slightly tender abdomen and dicrotic pulse were the rule rather than the exception. Just as in the uninoculated, all gradations of the disease were found. We have long been acquainted with the mild and ambulatory cases, difficult of diagnosis because of the mildness and frequent absence of many of the symptoms. Many such have probably occurred among our troops and remained undiagnosed. It is further possible that the number of cases that would fall into this class has been greatly increased by preventive inoculation. But of those numerous patients whom we have seen sick in hospital, there could be no doubt as to the clinical diagnosis.

Leukopenia.—White blood counts failed to detect a leukocytosis. On the other hand, the leukopenia was not so marked as it is described in the classical typhoid (Charts 8 and 9). The average white counts on successive days of the disease stood around 7,000. Some were higher and some were lower, but not a few are reported of from 2,000 to 4,000 per cubic millimeter. Realizing that our reports were being received from seventeen different laboratories and that the high counts might be due to variations in technic, we grouped all the reports from a single hospital in which cases of typhoid fever were unusually frequent. Here the average white counts on different days of the dis-

ease, as compared with the average for all hospitals, was lower, but not remarkably so (Chart 10).

In uncomplicated typhoid the white count averaged around 7,000. This figure agrees with that reported by Hawn, Hopkins and Meader.⁴ Whether this is due to a change resultant on vaccination or to other causes, it is hard to state. The presence of several real instances of leukopenia prove the possibility of such occurring in the antityphoid inoculated. The average white count during hemorrhage was 4,500; in perforation, 6,000; in lobar pneumonia complicating the disease, 12,000, and in bronchopneumonia, 9,000. These, again, are figures that agree with those for typhoid in the unvaccinated.

Fever.—Chart 11 shows the case of a man in hospital with an acute febrile disturbance who in the second week had the onset of a typical typhoid fever with steplike rise in the fever curve and a slow pulse; the fastigium starting in the second week of the disease, becoming definite in the third and fourth with increased rapidity of the pulse, and followed in the fifth week by lysis. In Chart 12 B is seen again the steplike rise and the tendency to a continued high fever during the

Chart 7.—Incidence and average day of appearance of symptoms and frequent complications in 270 cases of proved typhoid.

succeeding ten days. C, on the same chart, begun during the fastigium, shows that period and the following decline by lysis. Chart 13 G and I show relapses following rather mild initial courses.

4. Hawn, C. B.; Hopkins, J. D., and Meader, F. M.: Outbreak of Typhoid Fever Among American Troops in England, J. A. M. A. 72: 402 (Feb. 8) 1919.

The type of fever in vaccinated typhoid patients did not differ remarkably from that in the unvaccinated. The average day of cessation of fever was 26.9. Relapses occurred in 10 per cent. of the cases, and the average date of onset was the thirty-fifth.

Atropin Test.—This was performed in a small number of cases, and was usually found to be positive (no pulse increase over 20 beats a minute after 2 mg. of atropin subcutaneously). This was particularly the

Chart 8.—Average white blood counts in “uncomplicated” cases of proved typhoid arranged according to day of disease.

case during the first week, when the pulse was slow. It was often negative after the pulse rate had increased. We regard this test as of confirmatory value similar to such findings as a palpable spleen, which may be absent, and which again does occur in other diseases than typhoid.

Preliminary Diagnoses.—A word should here be given to the admission diagnoses of these cases of proved typhoid (Chart 14). Of 206 cases in which the entrance or provisional diagnosis was noted, 120 bore a diagnosis of respiratory disease, while only forty-nine were diagnosed as gastro-intestinal. This, again, is in accordance with our previous knowledge of the disease, the initial symptoms being not local but the general symptoms of acute infection with frequently a concomitant bronchitis.

Chart 9.—Maximum and minimum blood counts in “uncomplicated” cases of proved typhoid arranged according to day of disease.

Mortality.—Death occurred in 11 per cent. of the 270 cases studied, and the average day of death was the twenty-first.

LITERATURE

The foregoing clinical findings in typhoid fever are in accord with the observations of others. Labbé’s remarks:

The symptomatology has nothing characteristic. The same elements are present as among the unvaccinated, and they

appear in the same order. The onset is not marked by special symptoms. . . . During the fastigium the diarrhea is neither more nor less frequent. . . . At most, one could say that the abundant diarrheas are a little less frequent among the vaccinated.

TABLE 2.—OCCURRENCE OF ROSE SPOTS

Nature of Eruption	Vaccinated, per Cent.	Nonvaccinated, per Cent.
Absent.....	6*	10
Discrete.....	18	15
Average.....	40	53
Heavy.....	28	13
Very profuse.....	8	9

He suggests that the exanthem may be more profuse. His figures for the occurrence of rose spots are reproduced in Table 2. In summarizing these figures he states that the eruption was unusually intense in 36 per cent. of the vaccinated and in but 22 per cent. of the nonvaccinated, and concludes that although unusually intense eruptions also occur in the unvaccinated and although it is not an exclusive phenomenon of the vaccinated, the unusually heavy and confluent eruptions are more frequent among the latter. This may be true, as we have not made examinations with this particular point in view; but I would call attention to the fact that in Labbé’s figures the percentages of absent and discrete rose spots are about the same in the

Chart 10.—Comparison of average white blood counts for entire series with average blood counts reported from Camp Hospital 53.

two columns, as are also the percentages for the very profuse. The difference occurs in the two intermediate stages. It is frequently difficult to distinguish between two gradations so close together. Were the variations farther separated in the columns, the evidence would be more convincing.

Labbé, in discussing the rose spots, also states that they are frequently quite persistent, lasting as long as fifteen or twenty days. They may occur as early as the fourth day. Blood cultures in his experience are negative after the fourteenth day, although in the non-vaccinated they may be positive as late as the twenty-eighth. He further asserts that the febrile period is notably shortened in the vaccinated. Patients during the pyrexia are fully as sick and as toxic as are the unvaccinated; but instead of three or four weeks of fever, there are usually only two or three. After the defervescence there is no subsequent rise, but the gastro-intestinal symptoms persist. Relapse is decreased in frequency from 10 per cent. in the non-vaccinated to 3.5 in the inoculated. In the mortality he reports the greatest results. A death rate of 21.4 per cent. among the nonvaccinated is decreased to 2.4 per cent. among those who have received two or more injections.

How are we to reconcile these reports with our findings of a febrile period averaging twenty-seven days, positive blood cultures into the fourth week, 10 per cent. of relapses, and a mortality of 11 per cent.? It is true that we have many cases with short febrile period, but the figures clearly show that for these short cases

5. Labbé, Marcel: Ann. de méd. 3: 13, 1916.

we had a similar number with long duration, and that the average was as in the nonvaccinated. A positive blood culture is an absolute finding, whereas a negative culture proves nothing. I can only state that we had positive cultures after the second week. Our true mortality may well be under 11 per cent. I assume that to be too high rather than too low. Practically all severe cases of typhoid, especially in those who died, must have been recognized as such, whereas in hospi-

Chart 11.—Pulse and temperature in acute febrile disturbance; onset of typical typhoid in second week.

tals where there was no epidemic many lighter cases probably remained undiagnosed. Our true mortality was presumably below 11 per cent., but there is a wide interval between that figure and the 2.4 per cent. of Labbé, which requires further interpretation.

The reason for this discrepancy between figures is recognized as a possibility by Labbé. His report comprises a study of 154 individuals who had received from one to four inoculations of antityphoid vaccine. Practically none had received triple vaccine. Immunized against *Bacillus typhosus*, these men had become infected with one of the two paratyphoid organisms. Among these only fifteen were infected with the organism against which they were inoculated, and among them the mortality was 26.6 per cent., more than twice as high as our own mortality. These fifteen were diagnosed by positive blood cultures. The well known lower mortality in the paratyphoid infections has lowered Labbé's total mortality figures.

The clinical symptomatology among French troops, as described by Bernard and Paraf,⁶ unlike that of Labbé, is definitely divided into that of straight typhoid infection and of paratyphoid. Concerning the former, they remark:

Typhoid fever (among the vaccinated) has no peculiar characteristics which might indicate a modification of the disease resultant on a modification of the soil. The different classical forms are found with their usual characteristics. The mild forms present the usual appearance and evolution; few symptoms; no typhoid mental state; duration ten to fifteen days without complication, and simple convalescence. The moderately severe forms, common here as always, are the most frequent. They show nothing special, either in appearance of the symptoms, in the temperature curve, or in the progress or length of the disease. We remark that in four cases we found an unusually abundant eruption of rose spots and in one a total absence thereof. . . . The more serious cases showed meteorism, a thick, dry tongue, and lessening of the heart sounds, as they are among the nonvaccinated. It is worth while, however, to mention the extreme rarity of the serious complications.

The mortality in the twenty-six cases studied by these authors was 0 per cent., and the average severity (severe and fatal cases) was 26.9 per cent., as contrasted with 37.5 per cent. severity among the nonvaccinated. There is in their series a diminution in the gravity of the disease.

Campani and Gallotti,⁷ working on the Italian front, found in a study of 144 nonvaccinated civilians and 341 vaccinated typhoid and paratyphoid soldiers that the mortality in the vaccinated straight typhoid patients was 8.6 per cent. and in the paratyphoid A and B, 4.6 and 7.8 per cent., respectively, as compared with 20 per cent., 0 and 0 per cent. in the unvaccinated. They found that in both groups about 42 per cent. of the patients had febrile periods lasting into the fourth week, and that the average duration of fever was, in the soldiers, 24.5 days, and among the civilians, 28 days. They state that the febrile curve, instead of being irregular and low in the vaccinated, was high and decidedly more regular than among the nonvaccinated, and that relapse occurred more frequently among the former. Splenomegaly and nervous phenomena were more frequent among the vaccinated. They conclude that vaccination has lessened both the mortality and the severity of the disease.

Bourges⁸ reports in detail the case histories of five vaccinated men infected with *B. typhosus*, all of whom recovered. The descriptions are those of cases of classical typhoid.

Freund,⁹ reporting typhoid infection in the German army, concludes that among the vaccinated there are more remissions and intermissions, and a greater proportion of mild cases. The fever is milder, but the total duration of the disease is not shortened. There is no change in the frequency of complications or relapses resultant on vaccination. The mortality among the vaccinated is given by him as 8.3 per cent.

Hawn, Hopkins and Meader,⁴ describing thirty-eight cases studied in an outbreak among American troops

Chart 12.—Temperature in two cases.

in England, found clinical signs similar to our own. They described initial chills in 16 per cent., diarrhea in 58 per cent., constipation in 21 per cent., abdominal pain in 6 per cent., and epistaxis in 2.6 per cent. Among their thirty-eight cases rose spots were described in nineteen, palpable spleen in fifteen, and abdominal distention in nine. The average white counts ranged around 7,000 or less, and blood cultures were positive in twelve cases. The average duration

of the fever was thirty-five days, and the mortality in their series was 13.15 per cent. These findings among American troops in England corroborate ours for those in France.

Finally, the mortality for all troops in the American Expeditionary Forces from straight typhoid, between July 1, 1918, and May 31, 1919, was, for 1,242 cases, 13 per cent.

MORTALITY

Numerous observers have reported mortality results in the vaccinated. In Table 3 are given records of true typhoid in individuals immunized against *B. typhosus*.

It follows from a perusal of these varied results that

the final determination of the mortality in inoculated typhoid patients is yet to be made. Many of the figures quoted above are much lower than our own, and yet the average is not lower than the mortality of 7.6 per

The various and varying factors that influence the death rate in disease, and particularly in a disease like typhoid fever, can never be mathematically eliminated, and can be rendered negligible only when the mortality figures from all sources have become so great that they include numerous cases touched by every one of these factors and by all of their variations.

Chart 14.—Preliminary diagnosis in 206 cases of proved typhoid.

TIME RELATIONSHIP TO VACCINATION

Having ascertained that vaccination did not change the essential characteristics of the disease as it was found in the hospital and that it produced no such marked alteration in the incidence of complications or in the mortality as to be termed decisive, let us examine the other phase of the situation, the effect, if any, produced by varying intervals of time after the inoculations.

TABLE 4.—RELATIONSHIP BETWEEN TIME INTERVAL SINCE VACCINATION AND SEVERITY OF THE DISEASE IN TWO HUNDRED AND SEVEN CASES OF PROVED TYPHOID

First, as regards the severity of the disease: In 207 cases of *B. typhosus* infection in which the date of inoculation was obtainable and the severity of the disease could be determined, we were able to tabulate the data presented in Table 4.

More instructive information is obtained on computing the average severity of the disease (severe percentage combined with fatal percentage) for six month periods following inoculation (Table 5).

There is seen a small but progressive increase in severity with lapse of time after inoculation. If we accept only those months that show ten or more cases

as being sufficiently large numbers to give reliable information, we find for one month periods the following:

It appears that the average severity of the disease remained fairly constant throughout the first eight months following inoculation, after which it increased gradually.

The incidence of relapses during this period is not notably changed. During the first month relapses occurred in 10 per cent. and during the first eight months in 11.9 per cent., as compared with 10 per cent. for the total series. Likewise, complications occurred in 21.5 per cent. during the first month, in 23.2 per cent. during the first eight months, and in 33.5 per cent. during the entire period. The last figure becomes higher because in the nineteenth month two complications occurred in one case, giving a resultant percentage of 200.

The type of onset of the disease appears to be influenced by the lapse of time after vaccination. Acute onset predominated in the first month, when it occurred in eighteen out of twenty-nine cases. During all other months the onset usually was gradual. Sixteen out of the twenty-nine cases showed onset between the

seventh and the twelfth days after inoculation—the recognized usual incubation period for typhoid fever. Imperfect vaccine with unkilld organisms as a cause of these cases is a possibility, but in our opinion a very remote one. Results of laboratory accidents, both reported and some unreported but with which I am personally acquainted, incline us to the belief that if living typhoid organisms were inoculated through the skin into a healthy adult, the chances are that he would not develop typhoid fever. We are particularly convinced of this as regards attenuated cultures. Most cases of laboratory infection appear to be due to hand to mouth contagion.

We know that about ten days are required after the introduction of antigen, be it living organism or killed vaccine, before antibodies appear in abundance and, in the case of the former, before disease symptoms become manifest. We also know that until the reactive period the organisms multiply freely in the body. If a man is inoculated on the first day with reliable vaccine and on the fourth or fifth becomes infected through contaminated drinking water, the organisms will grow abundantly within the body for a time. But this time will not be as long as it would were he not vaccinated. In the latter case it would be from seven to fourteen, usually ten days, after infection. In the former it would be that interval after inoculation, when the anti-

bodies called out by the artificial antigen would be present in numbers and would act on the living, growing virus. This we postulate to be the explanation for the larger number of cases occurring in post-vaccinated at the end of the incubation period. Patients in this group with onset preceding the seventh day were probably infected before inoculation. All patients who fell ill with the disease during the first month after inoculation were in a camp where there was a small epidemic of typhoid at the time, and all were vaccinated with the lipovaccine.

(To be continued)

Clinical Notes, Suggestions, and New Instruments

BLOODLESS THORACOSTOMY

R. J. BEHAN, M.D., PITTSBURGH

There are so many methods of trocar drainage of empyema cavities that I have hesitated to suggest another. However, since most of these methods have certain defects and are cumbersome and difficult of application, I thought it would be wise to describe a method minus such difficulties that I have used for the last four years.

At present there does not exist much antagonism to puncture drainage of an empyemic cavity; but four years ago such a procedure was radical, and was regarded with a good deal of skepticism. It was contended that a wide hole in the chest wall was necessary for empyema drainage, and it was held that drainage could not be thoroughly established through a small opening. It was also held that if a small opening should be made into the chest wall and a drainage tube inserted through this opening, the impinging of the ribs against the tube would block the tube and cut off the drainage.

So many of the patients having either acute or chronic empyema are in such bad condition and are so feebly resistant that any operative interference is very dangerous, especially operative interference that entails shock. The removal of a rib, with the cutting, etc., that is associated, causes some shock and has an operative risk; but the pushing through the chest wall in an intercostal space of a trocar and a cannula, after the area has been thoroughly anesthetized, causes little shock and is associated with hardly any risk.

It was with the idea of developing an instrument which could be easily used, which would not collapse with rib pressure, and which could be obtained at a reasonable cost, that I devised an apparatus, and had Harvey Pierce & Co. of Philadelphia make it for me in 1915.

The apparatus consists of three essential elements.

First, a very long aspirating needle (*a*) with a detachable nipple (*b*) which will fit a record syringe (*c*). This needle is calibrated from the tip to the hilt in centimeters and has a large lumen.

Second, a trocar (*d*) and a cannula (*e*). The trocar is of the shape shown in the illustration. It consists of a blade portion with a handle bent almost at right angles. At the upper part of the trocar blade is a groove, made so that it will accommodate the long aspirating needle. Over the trocar can be sheathed a cannula, which is calibrated in centimeters from the tip to the hilt. Over this cannula is drawn a shoulder-piece or sleeve (*f*), which can be tightened and firmly fixed at any point on the cannula. This shoulder has on it, on each side, a slit through which a tape can be threaded. This tape is passed around the body of the patient and tied so that the cannula is held firmly in place. At the end of that part of the cannula which is external to the patient is a small hole through which a suture, which has been passed through a rubber retention catheter, (*g*), introduced through the cannula (after the trocar has been removed), may be threaded and tied.

This self-retaining catheter (*g*), with its obturator (*h*), is the third essential constituent of this apparatus.

The trocars and cannulas are in various sizes and lengths to allow for different widths of the intercostal spaces and the varying depths at which pus is found. The depth to which a cannula may be inserted may be so regulated by the adjustable sleeve or shoulder-piece on the cannula that an abscess of the lung, even some distance from the surface, may be drained without danger.

OPERATIVE TECHNIC

The empyema or abscess cavity is localized by physical examination and the roentgen-ray. Then the skin over the lung abscess or empyema is sterilized by tincture of iodine, and is anesthetized by procaine 1 per cent., so that the tissues down to and including the pleura are desensitized.

The large needle attached to a record syringe is now inserted. As soon as the tip of the needle has passed through the skin, the piston is drawn up in the barrel so that there is a constant negative pressure in the needle. The needle is now inserted directly toward the supposed location of the empyema or abscess.

As soon as the needle enters the pus cavity, pus is aspirated into the syringe by negative pressure. The syringe is detached and the needle is left in place. The depth at which pus is found is noted on the needle. The nipple of the needle is now removed.

Then the trocar with its cannula, the shoulder of which has been set at a little more than the depth indicated on the needle, is threaded on the obturator (shown in the illustration) and is pushed down over the needle into the cavity. The needle and trocar are now removed, the cannula being held in place by the fingers of the left hand of the operator. A rubber self-retaining catheter of a slightly larger size than the lumen of the cannula is now threaded on the obturator and is put on the stretch so that the portion which is to enter the cannula is of considerably less diameter than when in its normal state of tension. It is then pushed through the cannula into the pus cavity.

During these procedures a slight amount of air may enter the pleural cavity. Such entrance may be unavoidable, but is of no consequence. I have never found any ill resulting from it. However, aspiration of air generally does not occur, as the pus is at a greatly increased pressure and immediately drips out of the needle, or will run out of the catheter after it has been inserted. Immediately on the insertion of the catheter, after the obturator is withdrawn, I block off the catheter by placing on it a hemostat.

The tape, attached to the shoulder of the cannula, is tied around the chest of the patient. A piece of very thin gauze, well coated with petrolatum, is wound around the cannula beneath its shoulder. A suture is then passed through the catheter, which is held fixed in place at the proper depth. This suture is generally of linen or silk. As a further protection, the shoulder of the cannula may be sutured with silkworm gut or with linen to the skin.

On the catheter itself a two-way cock may be inserted. Most frequently we insert a rubber tube connection and drain into a bottle alongside the patient's bed, as is done for empyema of the gallbladder. It is also common with us to use the so-called Woulfe bottle drainage, and at the same time we have the patient blow the water from one of the bottles to another. If a rubber or glass Y has been placed on the tube, surgical solution of chlorinated soda (Dakin's solution) may be instilled through one of the arms of the Y, if it is necessary, or the solution may be run directly into the cavity through the catheter.

As a final dressing, gauze is applied around the tube and cannula, and the tapes passing around the chest are covered with adhesive plaster which has been moistened with ether, in order to make it stick.

RESULTS

I have used the foregoing method in numerous cases, and have invariably found it satisfactory. It has been adopted by my colleagues in the hospital, one of whom used it extensively during the influenza epidemic of 1918, and he states that in no case did he have any difficulty.

The entire method is very simple and causes absolutely no shock to the patient. Little patients who have been brought to our institution almost moribund have improved wonderfully from day to day with the trocar-cannula drainage inserted under a local anesthetic. I have used this method also in cases of lung abscess. In one case, that of a child, the abscess had communicated with a bronchus, so that for some time he had been coughing up pus. The abscess cavity was definitely located by the roentgen-ray. It was about 2 inches from the surface of the lung, in the third interspace in the anterior axillary line on the right side. The needle was inserted and pus was found. The drainage was then introduced, according to the technic described above. Considerable foul pus was evacuated. Immediately after drainage had been instituted, the disagreeable, foul sputum ceased.

The temperature dropped, and the child made a quick recovery, except for a persisting sinus, which was finally healed by the injection of Beck's paste.

In another case of lung abscess the patient inside of a week, after drainage had been instituted, began to take on flesh. The cough had ceased and there was no more foul sputum.

The apparatus is such that it enables us to reach deep-seated abscesses of the lung which, otherwise, would be inaccessible.

So far, I have had no hemorrhage, although I always, of

course, follow the needle which has localized the pus and has been left in place. I have allowed the cannula to remain in the chest wall for long periods. It does not seem to produce any necrosis of the surrounding tissues or of the adjacent ribs. The opening remains absolutely air-tight for at least eight or ten days; then if it leaks air somewhat, the leakage may be controlled for another week or ten days by smearing over and around the cannula large quantities of petrolatum.

As I have said, in no case have I encountered disagreeable or unsatisfactory after results.

Suite 6079, Jenkins Arcade Building.

Tobacco Smoking in Pulmonary Tuberculosis.—There is some conflict of opinion about the harmfulness of tobacco smoking in pulmonary tuberculosis, and at least one writer has tried to prove that it is actually beneficial. Most sanatoriums limit the time for smoking to half an hour after meals. Certainly, smoking before meals is definitely harmful in that it satisfies by numbing the appetite at the time when this ought to be keenest. Quite apart from the action of tobacco on the circulation, it is generally acknowledged that it is an irritant to the upper air passages. Many a patient will admit that he has more real sputum (not merely saliva) when he is smoking heavily than when he gives it up. Nevertheless, the psychologic factor is again so strong as to decide policy in this respect; and where men become miserable or restless when they are deprived of their tobacco, it is better to allow it in moderation after meals. Patients with laryngeal tuberculosis should be forbidden the use of tobacco altogether.—James Watt, *J. State Med.*, March, 1920.

STATE BOARD STATISTICS FOR 1919

ANNUAL PRESENTATION BY THE COUNCIL ON MEDICAL EDUCATION OF RESULTS OF STATE BOARD EXAMINATIONS

On pages 1084 to 1091 are three tables, A, B and C, giving in detail the results of the various state medical license examinations held during 1919. All state licensing boards sent in reports and the figures have been carefully verified.

Tables A and B, when read from left to right, show for each medical college named (a) the number of graduates appearing for examination in each state, (b) whether they passed or failed, (c) the total number examined during the year, (d) the number who passed, (e) the number who failed, (f) the percentage of failures, and (g) the number of states in which graduates of that school appeared for examination. Read from above downward, they give the results by states, showing (h) the number registered and rejected from each college, (i) the total numbers examined, registered and rejected, and (j) the percentage of rejections. The majority of graduates take the license examination in the state in which the college is located, as shown by the dark diagonal zone of figures passing from the upper left to the lower right corner of each table. These tables are worthy of careful study, since important deductions are possible. The marginal numbers will enable one to follow readily the line for any college.

GRADUATES OF ALL YEARS EXAMINED IN 1919

Table A shows the results for all candidates who took examinations in 1919, regardless of the years in which they graduated. This shows that altogether 4,736 candidates were examined last year, as compared with 3,637 in 1918, 4,730 in 1917, 4,850 in 1916 and 5,313 in 1915. This year shows an increase of 1,099. Previously, there had been a steady decrease since 1906 owing chiefly to (a) the larger registration through reciprocity, and (b) the general diminution in the number of medical colleges, students and graduates. The marked decrease last year was due to the enlistment of many physicians for military medical service. Of those examined this year, 14.3 per cent. failed, as compared with 13.3 in 1918, 14.1 per cent. in 1917, 15 per cent. in 1916 and 15.6 per cent. in 1915.

There were 79 medical colleges in the United States granting degrees in 1919 which had graduates examined, as compared with 80 in 1918, 89 in 1917 and 1916 and 93 in 1915. There has been a decrease of 74 since 1905, when graduates from 153 medical colleges were examined. The statistics covering schools which have ceased to exist are included in the line for "miscellaneous colleges."

Graduates of Canadian schools were examined in 22 states. The largest number, 23, were examined in New York, the next largest number being 8 examined in Massachusetts. The figures are given separately in order to show the number of candidates coming from each, and to show the successes of their graduates at the examinations. Altogether, 71 candidates from Canadian colleges were examined, of whom 22, or 31 per cent., failed.

Foreign graduates were examined in 17 states, the total examined being 67, and of this number 30, or 44.8 per cent., failed. In 1918, 45 foreign graduates were examined. The largest number of foreigners examined in any state in 1919 was 21 in California, where 9, or 42.9 per cent., failed.

CAUTION IN FORMING CONCLUSIONS

In making comparisons on the basis of these statistics, the reader must keep in mind (a) the number examined, since the larger the number of graduates examined, the more accurate is the finding; (b) the number of states in which a school's graduates have been examined, since the larger this number, the more accurate will be the conclusions; (c) the character of the board making the examination and the methods employed, since some boards refuse to examine graduates of inferior medical colleges, while others (see Table H) not only examine graduates of all medical colleges but also

admit osteopaths to the physicians' and surgeons' examination. Some boards also hold careful examinations which include practical laboratory and clinical tests, or they mark the papers more severely, while others, especially partisan boards, are very lenient. Although conditions are undergoing a gradual improvement, it is still true that the license examinations, as usually conducted, are much more lenient than those required in other countries. It is particularly important, in forming conclusions based on these statistics, to note for each college the states in which its graduates are not admitted to examination—information set forth with these statistics in Table D. A state board which admits to its examinations graduates of low-grade medical schools would be expected to have a higher percentage of failures.

UNDERGRADUATES AND OSTEOPATHS EXAMINED DURING 1919

For the last three years the few undergraduates examined have been accidental instances due evidently to imperfect credentials. In 1906, there were 703 undergraduates examined, and 342 were licensed. Colorado is now the only state which will knowingly admit nongraduates to its examinations, but only six have been licensed in that state in fourteen years, two having been so licensed this year. The door has been closed, therefore, against the admission to practice of those whose medical training is known to be incomplete. At present, however, some boards are registering as physicians and surgeons, by examination or by reciprocity, graduates of osteopathic colleges—no one of which compares favorably with the lowest grade Class C medical college—even though in two of these states—Colorado and Texas—the boards refuse to admit graduates of Class C medical schools to their examinations. (See Table D on pages 1092 and 1093.)

During 1919, in California, 28 graduates of osteopathic colleges were admitted to the regular examination for licenses as physicians and surgeons, and of this number 13, or 46.4 per cent., were granted licenses. In Colorado, of 25 osteopaths examined, 14, or 56 per cent., were granted licenses as physicians and surgeons (see Tables G and I). Two osteopaths were so licensed in Washington and one each in New Hampshire and Texas. Altogether 57 osteopaths were examined as physicians and of this number 31, or 54.4 per cent., passed.

RECENT GRADUATES EXAMINED DURING 1919

Table B gives the results for graduates of 1915 to 1919, inclusive, examined during 1919. This table is important, since it deals with recent graduates, and is, therefore, the fairest basis for comparison between colleges. Of all candidates examined in 1919, 3,904, or 82.4 per cent., were recent graduates, and of this number, 10.5 per cent. failed, as compared with 14.3 per cent. for all candidates.

OLD PRACTITIONERS EXAMINED DURING 1919

Table C is so arranged as to show in comparison the results for graduates of all years (first column), for recent graduates (second column), for graduates of 1914 and previous years (third column), and for graduates of 1919 (fourth column). Of the graduates of 1914 and previous years—"old practitioners"—767 were examined, and of this number 236, or 30.8 per cent., failed, as compared with 10.5 per cent. of failures for recent graduates. This high percentage of failures is due largely to the long time these candidates have been out of college and to the fact that they are commonly required to take the same examination as recent graduates. Justice to these older physicians, who have been licensed, but who, for good reasons, desire to change their locations, is a strong argument for the use of

(CONTINUED FROM PAGE 1083)

practical examinations by which they may show their skill in diagnosis and treatment, for a wider provision for reciprocity and for special percentage allowances for years of active practice. The total number of these candidates is diminishing each year as state licensing boards extend the provision for reciprocity, or for the endorsement, without further examination of licenses granted by other states where a physician's qualifications are otherwise satisfactory. As a rule, the states which do not have reciprocal relations with other states (Florida, Massachusetts, Montana and Oregon, see Table G) examined the largest numbers of old practitioners.

GRADUATES OF 1919 EXAMINED DURING 1919

Table C also gives the results for the graduates of 1919 who were examined during the year by the state boards, and shows that 2,422, or 51.1 per cent., of all candidates examined during the year, graduated in 1919, including nine who graduated from Canadian medical colleges. Educational statistics show that the medical colleges of the United States graduated 2,656 students last year (including 252 for whom diplomas were withheld until a year's internship in a hospital has been completed); therefore, 90.8 per cent. of all graduates in 1919 took examinations for license during that year. In some of the states, graduates in medicine are allowed to serve as hospital interns without first becoming licensed practitioners, which accounts for some of the remaining 9.2 per cent. Of the 1919 graduates examined, 101, or 4.2 per cent., failed, as compared with 5.5 per cent. in 1918, 5.7 per cent. in 1917; 7.4 per cent. in 1916 and 7.5 per cent. in 1915. A steady improvement in recent years in the qualifications of medical graduates is apparent from these figures.

NONRECOGNITION OF MEDICAL COLLEGES

Table D shows for each college, from official reports, the states in which its diplomas are not given unqualified recognition. Nonrecognition is expressed by different terms in different states. Some boards list colleges as "not in good standing;" some give them as "not reputable;" in New York full recognition is given only to colleges which are "registered," and in Michigan colleges are divided into groups, only those of Group 1 having full recognition. This table also shows the latest rating given to each college by the Council on Medical Education.

From the point of view of the prospective student who may be selecting a medical college, the facts in Table D are of extreme importance. There are 59 medical colleges now having complete recognition in all states. There are others for which the few instances of nonrecognition are due to certain technicalities in state board requirements. If the student gets his medical training in one of the remaining 18 colleges, he will find on graduation that his diploma is not recognized in from 7 to 42 states!

Without the information published in Table D, these state board statistics would be not merely incomplete—they would be actually misleading. For example, 35 graduates of the Kansas City (Mo.) College of Medicine and Surgery were examined in 1919. Of these, 33 (94 per cent.) were examined by the Arkansas Board of Eclectic Medical Examiners and all but one passed. The statistics show only 5.7 per cent of failures, which would make this college appear to belong among the better grade medical schools of the country. Quite different the picture, however, when the facts are known, as set forth in Table D, that this college is reported as not recognized in its home state and in 36 other states, and that for its very existence it depends on the acceptance of its graduates by the Eclectic Board of Arkansas! The figures obtained for the last several years indicate that neither the Kansas City College of Medicine and Surgery nor the Arkansas Eclectic Board could exist without the other.

During the seven years this table has been published, the percentages of fully recognized colleges were, respectively, 29.0, 32.3, 43.7, 65.6, 57.3, 61.3 and 67.8. This shows a decided improvement in the medical colleges. Forty-two state licensing boards, to some extent at least, are now utilizing their legal power to refuse recognition to medical colleges which do not meet the requirements in the respective states. In the other eight states, however (including Alaska and the District of Columbia), this table indicates either that the practice acts do not give the boards authority to enforce a requirement of reasonable standards, or else that the boards are not exercising that authority. It is evident that if the graduates of low standard medical colleges are not eligible for license in the majority of states, they will flock to the other eight which still grant them recognition. These eight states—Alaska, Arizona, Massachusetts, Nebraska, Nevada, Oregon, Utah and the District of Columbia, therefore, will

(CONTINUED ON PAGE 1094)

+ Classification revised to March 15, 1920.

1. Formerly the Chicago Hospital College of Medicine. Has advertised also under the name of "Fort Dearborn Hospital School."
2. Suspended medical teaching in 1918, but retains a nominal existence until 1921 in order to grant degrees to the three remaining classes which are completing their medical instruction elsewhere.
3. This college claims to be an eclectic college, but is reported as not recognized by the National Eclectic Medical Association. It is an offshoot of the Eclectic Medical University, an institution

(x) According to official reports the licensing boards of the states thus indicated do not grant full recognition to, or have taken action refusing to admit to their examinations graduates of, the college marked by this letter—x

(CONTINUED FROM PAGE 1091)

remain the dumping ground for the output of low grade medical colleges, until the licensing boards obtain the needed legal authority, and until they take action in the matter. Arkansas, Florida and Connecticut are also registering through their separate sectarian licensing boards graduates of medical colleges not recognized in the majority of other states. It is reported that no examinations were held during the year by the Arkansas Homeopathic Board, and from the Florida Eclectic Board no report was received.

TABLE 1.—RECOGNITION OF MEDICAL COLLEGES (BASED ON TABLE D)

	Number of Colleges
Recognized by all state boards.....	59
Not recognized by 1 or 2 state boards.....	10
Not recognized by 7 to 17 state boards.....	9
Not recognized by 37 to 42 state boards.....	9
Total.....	87

STUDY OF TOTALS AND PERCENTAGES

A study of totals and percentages as compared with previous years is of interest. The number examined in 1919 was 1,099 more than in 1918; six more than in 1917; 114 less than in 1916, and 1,577 less than in 1915. Statistics regarding physicians licensed in the various states by reciprocity and by other methods are given in Tables G, H, I, J and K. By all methods—examination, reciprocity, under exemption, etc.

—6,584 physicians were licensed during 1919, or 2,399 more than in 1918, 1,161 more than in 1917, 1,712 more than in

TABLE 2.—RESULTS FOR THIS AND PREVIOUS YEARS

1916, but 1,281 less than in 1906, when 7,865 physicians were licensed.

Other deductions from the larger tables, presented in Tables E and F, are worthy of special study.

This table is interesting, since it gives data relating to the 34 larger medical colleges arranged according to the number of graduates examined. This allows of comparison between colleges having classes of nearly equal size. Jefferson Medical College had the largest number of graduates examined in 1919. The position was held by the Chicago College of Medicine and Surgery in 1913 to 1918, inclusive, by the University of Illinois College of Medicine in 1906, 1907 and 1912; in 1908 by Jefferson Medical College, and in 1909, 1910 and 1911 by the University of Louisville Medical Department. The first place from the standpoint of the number examined, however, does not always mean first place from the standpoint of scholarship. Note the percentages of failures. The five highest failure percentages are for Meharry Medical College, 50.4; Chicago Medical School (formerly Chicago Hospital College of Medicine), 45.2; Medical College of Virginia, 35.6; University of Louisville

Medical Department, 34.8, and the New York Homeopathic Medical College and Flower Hospital, 33.7.

Of the 14 colleges having 100 or more examined, eight have failure percentages of less than 10, while six stand out prominently with large failure percentages. Of the 20 colleges having between 40 and 100 graduates examined, 12 had failure percentages of less than 10, 15 had failure percentages between 10 and 20, and 3 had failure percentages of over 20 per cent.

The average percentage of failures for these larger colleges for graduates of 1914 and previous years was 24.5; for graduates of 1915 to 1919, inclusive (recent graduates), 10.0; for graduates of 1919, 9.1 and for graduates of all years, 11.4. Of the 4,258 graduates of the 82 colleges in the United States which had graduates examined by state boards in 1919, these larger (41.5 per cent. of all) schools furnished 3,229, or 75.6 per cent., of the graduates examined.

STUDY OF LARGER COLLEGES

Table E is also based on the three large tables, and gives the results of state board examinations as they affect the thirty-four largest medical colleges. Although these colleges represent 41.5 per cent. of the eighty-two medical colleges in the United States having graduates examined, in 1919 they furnished 75.6 per cent. of all candidates for license coming from medical schools of the United States. This table shows, also, that the graduating of large classes by a

This table gives the number of candidates registered and rejected on examination by each state during each of the last five years. The last four columns give the totals for the five years and the percentage rejected by each state. Compare this table with Table H.

Four states registered over 1,000 candidates by examination in the five years, these being New York, Illinois, Massachusetts and Pennsylvania. Over 2,000 were registered in only two states, New York with 2,824 and Illinois with 2,285. Altogether 19,884 physicians were registered by examination in five years, an average of 3,977 each year.

The five highest percentages of rejections for the five years were in South Carolina, 35.9; Alabama, 35.7; North Dakota, 29.5; Montana, 29.4; Connecticut, 24.9, and California, 24.4. Until 1916 Massachusetts, Oregon and Tennessee included nongraduates among those examined, and for that reason would be expected to have higher percentages rejected. On the other hand, in several states the boards refused to recognize certain colleges and eliminated many candidates prior to the examination by a careful scrutiny of credentials, and as a result the percentages of failures at the examinations are lower than otherwise would be the case. For example, Ohio rejected only 3.1 per cent. of those who took their examinations, but graduates of eleven medical colleges are not eligible for admission to the examinations. This table therefore should be studied in connection with Table D.

The lowest failure percentages were in Vermont, 0.9; Minnesota, 2.0; Washington, 2.3; Idaho, 2.5; Ohio, 3.1, and Michigan, 3.3.

medical college does not prove excellence of teaching, since five of these have high failure percentages. The larger the college from the standpoint of students and graduates, the more serious is inferior teaching ability, as indicated by a high failure percentage. In fairness both to medical students and to the public, such schools should strengthen their teaching facilities or reduce the size of their classes.

U. S. Territories and Possessions.....	19	8	27
Totals.....	3,495	530	35	2,459	65	6,584

This table shows the total number registered during 1919 in each state by the various methods. The first three columns show those registered by examination; the first column showing the recent graduates registered, the second column the old practitioners (graduates of 1914 and previous years) and the third column shows a few nongraduates, graduates of nondescript colleges and some osteopaths who were given licenses as physicians and surgeons. The fourth column shows the number licensed through reciprocity, by endorsement of other state licenses and by certificates of the National Board of Medical Examiners. The fifth column shows those licensed under various exemption clauses in the practice acts, such as because of national fame or by recognition of diplomas (New Mexico). California licensed as physicians 13 out of 28 graduates of osteopathic colleges, and Colorado so licensed 14 out of 25 osteopaths.

It is interesting to note that states like Arizona, Florida, Massachusetts and New York, which have no reciprocal relations or which reciprocate with only a few other states, have registered by examination the largest numbers of old practitioners. The large registration through reciprocity in California is due to the liberal provision in the recent medical practice act providing for the recognition of licenses granted in other states. No reciprocal registrations were reported for eight states.

The last column shows the total number of physicians registered by all methods in each state during the year. Four states registered over 300 each, these being New York, 711; Illinois, 568; California, 445, and Massachusetts, 305. Thirteen states registered less than 50 each. The largest registration was in New York, and the smallest number was 18 each in New Hampshire and North Dakota. The total registered by all methods was 6,584, an increase of 2,309 above the total registered in 1918. Of this increase, 1,487, or 59.5 per cent., were through reciprocal registration.

TOTALS EXAMINED IN FIVE YEARS

Table F shows the number registered and the number rejected in each state for each of the past five years. A comparison of this table with the statistics in the last educational number of THE JOURNAL (Aug. 16, 1919, p. 513, Table 12) shows—what would be expected—that the states having the several largest numbers of medical graduates, examined the largest numbers of physicians. New York leads, having examined 3,600 candidates in five years, followed by Illinois with 2,694. The five states having the next

U. S. Possessions.....	6	11	2	1	27	47
Totals.....	5,872	5,461	5,423	4,185	6,584	27,525

This table shows the totals registered in each state during each of the last five years. In some states it will be noted that there has been a gradual decrease during the first four years and a large increase in 1919. In others this increase has not been so large. The totals also are given for the entire five years. It will be noted that seven states registered over 1,000 physicians, the largest number being in New York with 3,044 followed by Illinois with 2,521, California with 1,841, Ohio with 1,177, Pennsylvania with 1,170, Massachusetts with 1,156 and Missouri with 1,099. Omitting the outlying territories the lowest registration during the five years was in New Hampshire, where only 94 physicians were registered, followed by Rhode Island and South Dakota each having 108, Delaware with 109, Nevada with 114, North Dakota with 115 and Wyoming with 119.

In the five years there were altogether 27,525 registrations, an average of 5,505 each year.

highest numbers are Massachusetts with 1,362, Pennsylvania with 1,182, California with 1,098, Missouri with 875 and Ohio with 840.

TOTAL REGISTRATION IN 1919

The tables thus far described have referred only to the results of examinations and to those registered on that basis. Table G, however, shows the total number who received licenses in each state, including those registered by examination, by reciprocity and under various exemption clauses. Altogether 6,584 physicians were registered by all methods during 1919, as compared with 4,185 in 1918, 5,423 in 1917, 5,461 in 1916, 5,872 in 1915 and 5,797 in 1914. The total

registered in 1918—4,185—was the lowest number registered in any year since the publication of these statistics was begun. This was undoubtedly due to the war. This year the total is increased by 2,399 and is the largest number since 1912. Of the increase, 1,487, or 59.5 per cent., were reciprocal registrations.

By reciprocity or under exemption clauses, 2,524 were licensed in 1919 as compared with 1,031 in 1918, 1,362 in 1917, 1,338 in 1916 and 1,386 in 1915.

Over 100 were registered by all methods in twenty-three states; over 200 in nine, and over 300 in four, the largest numbers registered being 711 in New York, 568 in Illinois, 445 in California and 305 in Massachusetts. Of those licensed in California 336, or 75.5 per cent., were registered by the endorsement of licenses granted by the boards of other states. California also registered as physicians and surgeons 13 graduates of osteopathic colleges. Fourteen osteopaths were so licensed in Colorado, 2 in Washington and one each in New Hampshire and Texas. Texas also registered 36 osteopaths by reciprocity.

TOTAL REGISTRATION IN FIVE YEARS

Table H permits the reader to compare the registrations in each state for the last five years. There was a decrease from 1915 until 1918. The decrease of 1,238 in 1918 was due undoubtedly to war conditions. A rebound is seen, however, in 1919, when there was an increase of 2,399. It is interesting to compare the registrations in different states. For example, in 1918 Massachusetts had an increase in the number of registrations regardless of the general decrease in the majority of states. Massachusetts was one of the states which also in 1919 showed an increase beyond what would be expected by the general increase. Since Massachusetts does not have reciprocal relations with other states, this increase is apparently due to the faulty medical practice act in that state, where the board is not given authority to refuse recognition to low grade medical colleges and cannot insist on reasonable standards of preliminary education. Attention is called also to the figures in 1919 for Arkansas, California, Connecticut, Minnesota, Nebraska, Texas, Wisconsin and Washington, in which states the registrations are larger than would be expected with the general increase in registrations. In California and Texas this seems to be due to the unusually generous provision for or the administration of reciprocity. In Arkansas and Connecticut, although the regular medical boards exact fairly high qualifications, there are generous sectarian boards which are not so particular. In Nebraska, only a high school education is required as the minimum standard of preliminary education. In Minnesota and Wisconsin, during 1919 generous provision was made for registering, without further examination, physicians who had been in the government medical services.

On the other hand, it will be noted that in several states, registrations in 1919 are less than in 1918 or are much smaller than would be expected with the general increase in registrations. In Vermont, there was a lower registration than in 1918, while in Indiana, Kentucky, Montana, New Hampshire, North Dakota and Oregon, the registrations are smaller than would be expected. It will be noted meanwhile that New Hampshire had the lowest number registered in the five years, while the largest number registered was in New York. This table would be interesting in connection with a study of the distribution of physicians in the United States.

MEDICAL TRAINING OF APPLICANTS LICENSED IN 1918

Table I is of special interest, since it shows for each state the numbers of candidates coming from medical schools rated in classes A, B and C, thereby indicating the character of the medical training of the candidates licensed during 1918. Of the 6,584 candidates registered, 4,060 were licensed by examination and 2,524 by reciprocity or on presentation of acceptable credentials. Those who graduated prior to 1907, when the first classification of medical colleges was completed by the Council on Medical Education, are included among those graduating from "Miscellaneous Col-

leges." Among the graduates of Class C schools are included 31 graduates of osteopathic colleges who were licensed as physicians in California, Colorado, Washington, New Hampshire and Texas. The Texas totals of Class C candidates would be increased if the 36 osteopaths who were licensed by reciprocity received licenses as physicians. Altogether, of the 6,584 candidates registered in 1919, 4,368, or 66.4 per cent., were graduates of Class A medical schools; 872, or 13.2 per cent., were from Class B schools; 278, or 4.2 per cent., were from Class C schools, and for 1,066, or 16.2 per cent., the colleges are unclassified.

As will be noted, the largest numbers of Class C graduates were licensed in Illinois with 38; Arkansas, with 33; Colorado, with 30, and California and Tennessee each with 23. All of the Class C graduates registered in Arkansas were licensed by the Eclectic Board.

Illinois registered 129 Class B graduates, the largest number, followed by California, with 69; New York, with 66;

Ohio with 51 and Oklahoma with 45. Oklahoma and Tennessee licensed more graduates of Class B and Class C colleges than of Class A graduates.

Only Class A graduates were registered either by examination or by reciprocity in Mississippi, South Carolina and Vermont.

It is evident that in several states, particularly, more care should be taken in the recognition of medical colleges, or better methods of examination should be adopted which will provide better safeguards against those not having adequate education.

SOURCE OF CANDIDATES REGISTERED IN THREE YEARS

Of the 6,584 physicians registered by all methods in 1919, 4,368, or 66.4 per cent., graduated from Class A medical colleges; 872, or 13.2 per cent., were from Class B medical colleges; and 278, or 4.2 per cent., were from Class C medical colleges. Of all candidates examined, 1,066, or 16.2 per

	Totals.....	3,102	499	192	267	4,060	1,266	373	86	799	2,524	4,363	872	278	1,066	6,584	

1. Of the 130 physicians licensed in Arkansas, the Regular Board licensed by examination 12 Class A, 12 Class B and 10 miscellaneous graduates and by reciprocity 19 Class A, 21 Class B and 20 miscellaneous graduates, a total of 94. The Eclectic Board licensed by examination all of the 33 Class C graduates and 2 of the miscellaneous graduates. The Homeopathic Board reported no candidates licensed either by examination or by reciprocity.

2. Of the 30 graduates of Class C colleges licensed in California, 13 were graduates of osteopathic colleges which are not generally recognized as medical colleges by state licensing boards. Altogether 28 osteopaths were admitted to the examination for licensure as physicians and 13 were licensed.

3. Of the 23 graduates of Class C colleges licensed in Colorado, 14 were graduates of osteopathic colleges, institutions inferior in most respects to Class C medical schools which are reported as not recognized in Colorado.

4. Texas licensed 1 Class C graduate by examination (although Class C colleges are reported as not recognized) and 15 Class C graduates (excluding 36 osteopaths) were licensed by reciprocity, a total of 16.

This table shows the classification of the colleges from which most of the physicians graduated who were licensed in 1919. Graduates of col-

leges which became extinct prior to 1907 who were examined, and all reciprocity licensees who graduated prior to 1907, are unclassified and included under "miscellaneous" since it was in 1907 that the Council on Medical Education completed its first classification of all medical colleges.

It will be seen that sixteen states accepted altogether 46 Class C graduates through reciprocity where they did not license any by examination. On the whole, however, 192 were licensed by examination where only 86 were registered through reciprocity.

By both examination and reciprocity, the largest numbers of Class C graduates were licensed in Illinois, 38; Arkansas, 33; California, 30; Colorado and Tennessee, each 23; Massachusetts, 19 and Texas, 16; The Texas figures would be increased by 36 if the osteopaths registered by reciprocity were granted licenses as physicians. The largest numbers of Class B graduates were licensed in Illinois, 129; California, 69; New York, 66; Ohio, 51; Oklahoma, 45; Texas, 38 and Arkansas, 34.

Of all physicians licensed, 4,368, or 66.4 per cent., were graduates of Class A medical schools; 872, or 13.2 per cent., from Class B schools; 278, or 4.2 per cent., from Class C schools, and 1,066, or 16.2 per cent., from foreign and miscellaneous colleges.

TABLE J.—PHYSICIANS REGISTERED THROUGH RECIPROCITY BY STATE EXAMINING BOARDS DURING 1919

[illegible]

* U. S. Army, Navy and Public Health Service.

This table shows the number of physicians registered by each state through reciprocity during 1919. Read from left to right, it shows the total number of physicians registered through reciprocity in the state named and at the top of such candidates coming from each of the states named at the top of the various columns. Read from above downward the figures show the number of physicians who left the state named at the head of the column and went to each of the states named in the corresponding lines, and at the bottom the total number of candidates leaving the state to go elsewhere. For example, read from left to right the table shows that Delaware registered nine candidates through reciprocity in 1919 and that, of these candidates one each came from the District of Columbia, New Jersey and Vermont and three each

from New York and Pennsylvania. Read from above downward the table shows that from Delaware one candidate each went to California, Illinois, New Jersey and Ohio, and two each went to New York and Pennsylvania, the total leaving the state to go elsewhere being eight. The line at the bottom shows in what states physicians who registered through reciprocity obtained their original licenses. From Illinois 325 candidates, the largest number, obtained their original licenses. New York follows with 197, Missouri with 144, Tennessee with 124 and Pennsylvania with 113. The total number licensed by indorsement of licenses or certificates obtained in other states was 2,459. This total does not include 36 osteopaths who evidently were granted licenses as physicians and surgeons in Texas through reciprocity with osteopathic boards of other states.

							Totals.....	1314	1271	1279	972	2459	7293

This table shows that 7,295 candidates were registered through reciprocity during the last five years. Registration by reciprocity gradually increased from 1905 to 1914, since which time there has been a gradual decrease as the total of physicians licensed by other methods has decreased. In 1918 there was a marked decrease in the total registered due largely to the war. This year there was an increase of 1,487 due

to a large migration following the return from military service. It will be noted that 130 were registered in 1919 on this basis. A study of the totals for the different states shows that of the 7,295 registered during the five years 1,002, or 13.7 per cent., obtained their original licenses in Illinois. New York could easily lead Illinois but reciprocal relations have been established with only six other states.

cent., came from medical colleges which have ceased to exist and from foreign medical colleges. By comparing these figures with the results for 1917 and 1918 as shown in Table 3, it is noteworthy that the percentages from Class B

TABLE 3.—SOURCE OF PHYSICIANS LICENSED IN THREE YEARS

Year	Medical Colleges in						Miscellaneous and Foreign Colleges		Total
	Class A		Class B		Class C		Num-ber	Per Cent.	
	Num-ber	Per Cent.	Num-ber	Per Cent.	Num-ber	Per Cent.			
1917.....	3,309	62.1	968	18.2	297	5.3	769	14.4	5,423
1918.....	2,456	58.7	682	16.3	342	8.2	705	16.8	4,185

Totals.....	10,193	63.0	2,542	15.7	917	5.6	2,540	15.7	16,192

and Class C colleges are steadily decreasing in spite of the fact that, in a few states, osteopaths are being licensed as physicians and surgeons.

TABLE L.—STATE REQUIREMENTS OF PRELIMINARY EDUCATION

There are now forty states which have adopted requirements of preliminary education in addition to a standard four-year high school education. Of this number 32 now require the two year standard. These states, the number of college years required and the time the higher requirements became or become effective are as follows:

State Examining Board of	One Year of College Work		Two Years of College Work

* Require a four-year high school education or its equivalent.

¹ No fixed standard.

1. The higher standards in Arkansas and Florida are evidently not enforced by the sectarian licensing boards of those states.

REGISTRATION BY RECIPROcity

Table J gives those registered without examination on presentation of satisfactory credentials, which included a license issued by some other state. This is commonly

referred to as "reciprocity," which conveys the idea that the state which accepts a license of another must be granted the same courtesy by the state issuing the original license. The term does not always apply, however, since some state boards—Arizona, California, Colorado, Delaware, Maryland, New Hampshire, New Jersey and North Carolina, as examples—accept the physician's credentials, if satisfactory, whether or not the state board issuing the original license returns the favor. Had not reciprocal relations been established by the forty states shown in Table J, 2,458 physicians—many of whom had been in practice for ten or more years—would have been compelled to undergo the ordeal of a second trying examination. This year 130 physicians were registered without examination, largely in Minnesota and Wisconsin, on the basis of their having been commissioned in the government medical services.

Table K shows in what states were granted the original licenses of those who were registered elsewhere under the

TABLE M.—ADVANCES IN STATE LICENSE REQUIREMENTS IN SIXTEEN YEARS

1. District of Columbia, Massachusetts and Wyoming.

2. Idaho, Oregon and the states named in Footnote 1.

3. See Table L.

4. Colorado.

5. New Mexico.

6. Pennsylvania, 1914; New Jersey, 1916; Alaska, 1917; Rhode Island, 1917; North Dakota, 1918; Washington, 1919; Illinois and Michigan, 1922; Iowa, 1923, and Texas, 1924.

7. District of Columbia, Massachusetts, Utah, Washington and Wyoming.

8. In three states, Arkansas, Connecticut and Florida, each of which has three separate boards, only the regular (nonsectarian) boards have refused recognition to low standard medical colleges and have enforced higher standards of preliminary education.

9. Alaska, Arizona, Nebraska, Nevada and the states named in Footnote 7.

10. Alaska, Arizona, Connecticut, Florida, Massachusetts, Rhode Island. To this list should be added the outlying territories of Canal Zone, Philippine Islands and Porto Rico, which have no provision for reciprocity.

11. Multiple boards still remain in Arkansas, Connecticut, District of Columbia, Florida, Louisiana and Maryland.

reciprocity provision during the last five years. Of the 7,294 physicians licensed through reciprocity during the last five years, the largest number coming from any one state was 1,002, who obtained their original licenses in Illinois. Although New York has a larger number of medical college graduates each year than Illinois,² only 511 physicians obtained original licenses in New York and registered elsewhere through reciprocity in the last five years. This is accounted for by the fact that Illinois has reciprocal relations with twenty-five other states, while New York has established such relations with only six.

IMPROVED STANDARDS OF LICENSURE

Table L shows the states which have adopted one or two years of college work as a minimum standard of preliminary education for those who seek the license to practice medicine in those states. The first and third columns show, respectively, when the one year and the two years of premedical

college work affects students matriculating in medical colleges, and the second and fourth columns give the years in and after which all applicants for licenses in the various states are affected by the increased requirements. This table shows the rapidity with which state board requirements of preliminary education have been advanced since 1908, prior to which no state was requiring more than a four-year high school education. As will be noted, there are now forty states which have adopted the higher standard, and thirty-two of these require as a minimum *two years* of premedical college work. It is understood that in every instance the one or two years of collegiate work must have included courses in physics, chemistry and biology.

In Table M the advance in standards of licensure is shown for all states since 1904. The most marked increase is in regard to the requirement of collegiate work in forty states as referred to in Table L. The next greatest increase (thirty-seven) is in the number of states—now forty-two—which are refusing to recognize low-grade medical colleges. Although, as shown in the third column, marked improvements have been made in state requirements for licensure, nevertheless, as indicated by the last column, there is still room for further improvement. The greatest needs are for a wider adoption of the requirement of the hospital intern year, the standard of two years of premedical college work, and—a matter of more vital importance—a more general and larger use of practical tests in the examinations. The states in which the boards are making really effective use of such examinations are Illinois, Massachusetts, Minnesota, North Dakota, Ohio and South Dakota. They are being followed to a greater or less extent in a few other states.

HOSPITAL INTERN YEAR

The hospital intern year has been adopted as an essential qualification for the license to practice in ten states, becoming effective in different years, as follows:

State Board of	Affects Student Matriculants	Affects All Applicants
Pennsylvania	1909-10	1914
New Jersey	1911-12	1916
Alaska	1912-13	1917
Rhode Island	1913-14	1917
North Dakota	1913-14	1918
Washington	1914-15	1919
Illinois	1917-18	1922
Michigan	1917-18	1922
Iowa	1918-19	1923
Texas	1919-20	1924

RECOGNITION OF GOVERNMENT EXAMINATION

The examination given under federal authority, which should be generally recognized by all state licensing boards as a qualification for license to practice medicine, is that given to medical officers of the United States Army, Navy, and Public Health Service. In fact, retired officers from the services mentioned are now eligible to receive licenses without further examination in

Alabama	Illinois	Virginia
California	North Dakota	Wisconsin
Colorado	Porto Rico	

This has been interpreted in most of the above states to apply only to those who were admitted to the government services under the strict examination which prevailed prior to the entrance of the United States in the World War and not to those who were commissioned after the admission requirements were relaxed. In Wisconsin, however, 76 physicians were licensed following their discharge from the government services. In Minnesota in April, 1919, a special law was enacted empowering the licensing board to register without examination physicians who had been in the government medical service overseas. Pennsylvania and Virginia licensed, respectively, 19 and 41 government medical officers following their discharge.

NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners, which was organized in 1915, consists of fifteen members, including the Surgeon-Generals of the Army, Navy and Public Health Service, and one other representative of each of those ser-

vices, three representatives of the state medical licensing boards and six members appointed at large. Up to Dec. 31, 1919, seven examinations had been held as shown in the following tabulation:

Date of Examination	Where Held	Total Examined	Passed	Failed	Percentage Failed
Oct., 1916	Washington	10	5	5	50.0
June, 1917	Washington	12	9	3	33.3
Oct., 1917	Chicago	28	22	6	21.5
Jan., 1918	New York	20	18	2	10.0
Apr., 1918	Ft. Riley, Ft. Ogle- thorpe	23	18	5	26.1
Dec., 1918	Chicago, New York	16	15	1	6.3
June, 1919	Philadelphia	52	51	1	1.9
Totals.....		161	138	23	14.3

Thirty medical schools were represented and the results were as follows:

College	Total Examined	Passed	Failed	Percentage Failed
Boston University S. of M.....	1	1	0	0.0
Columbia Univ. Coll. of P. & S....	11	11	0	0.0
Cornell Univ. Med. College.....	4	4	0	0.0
Emory University School of Med..	1	1	0	0.0
Georgetown University	1	1	0	0.0
Harvard University M. S.....	9	9	0	0.0
Howard Univ. School of Med.....	1	0	1	100.0

Rush Medical College.....	34	28	6	23.5
State Univ. of Iowa C. of M.....	3	2	1	33.3
Univ. and Bellevue Hosp. M. C....	1	0	1	100.0
University of Buffalo M. D.....	1	1	0	0.0
University of California M. S.....	1	1	0	0.0
University of Colorado S. of M....	1	1	0	0.0
University of Maryland S. of M....	1	1	0	0.0
University of Michigan M. S.....	3	1	2	66.7
University of Minnesota M. S.....	2	1	1	50.0
University of Nebraska C. of M....	1	1	0	0.0
University of Penna. S. of M.....	39	38	1	2.6
University of Pittsburgh S. of M....	1	1	0	0.0
University of Texas Dept. of M....	3	3	0	0.0
University of Utrecht	1	1	0	0.0
University of Va. Dept. of M.....	1	1	0	0.0
Western Reserve Univ. S. of M....	1	1	0	0.0
Woman's Medical College.....	1	1	0	0.0
Yale University School of Med....	1	1	0	0.0
Totals.....	161	138	23	14.3

Holders of certificates from the National Board of Medical Examiners will be registered without further examination in the following twenty states:

Alabama	Kentucky	North Dakota
Colorado	Maryland	Pennsylvania
Delaware	Minnesota	Rhode Island
Florida	Nebraska	South Carolina
Georgia	New Hampshire	Vermont
Idaho	New Jersey	Virginia
Iowa	North Carolina	

When the permanence of the National Board of Medical Examiners is established and the high character of its examinations is more generally recognized, it is quite probable that its certificate will be recognized by the licensing boards of a larger number, if not of all states.

IN CONCLUSION

In the gathering and publication of these statistics, the endeavor has been to give a fair presentation of facts, a knowledge of which is always beneficial. This annual presentation of the results of state license examinations has had a powerful influence on medical education and medical licensure in this country. We reiterate our acknowledgments to the state licensing boards for their ready cooperation and the complete reports which have been furnished. For the verification of all figures, the reports and data furnished by medical colleges have been of much value. We have no doubt that the information here published will be of service not only to the medical colleges and to the state boards, but also to the public, since the end-result is better qualified physicians.

STATISTICS OF THE STATE BOARD EXAMINATIONS

We publish this week, for the seventeenth consecutive year, statistics based on official reports of examinations conducted by state medical boards, and of registrations by reciprocity and other methods. During these seventeen years the work has had the hearty support and cooperation of the executive officers of the various state licensing boards, who have furnished reports of their examinations. Every report has been carefully checked with alumni lists furnished by the deans of the medical colleges, and by this cross-checking, errors have been corrected and the state boards concerned have been notified. Thus, not only have these statistics been made accurate and reliable, but also state board records have been corrected. We express our acknowledgments for the splendid cooperation of the officers of both the state licensing boards and the medical colleges by which the publication of these statistics has been made possible.

NO PROTECTION AGAINST INCOMPETENTS IN ARKANSAS

These statistics are of great importance as they relate to medical education and to medical licensure. For each state they show the number and character of physicians admitted to examinations; the character of the colleges from which they graduated; the numbers registered or rejected, and the proportion rejected. The material is so arranged that the facts regarding any one college or any one state can be compared with those, respectively, of all other colleges and states. Figures show that in some states people are well protected against illiterate and incompetent physicians, while in others, in varying degrees, the opposite situation prevails. A glaring instance relates to Arkansas, where, in spite of what the regular board of medical examiners is doing to enforce reasonably high educational standards and methods of licensure, thirty-six physicians were licensed who could not meet its requirements. This was because of the existence of a separate board of eclectic examiners. Among other applicants, this board examined thirty-three graduates of a nominally eclectic medical school, the Kansas City

College of Medicine and Surgery, and licensed all but one of them, even though it was well known that this college is not recognized by the licensing board of Missouri—its home state—and by the boards of thirty-six other states. And this has been going on for several years. Indeed, the reports seem to indicate that neither the Arkansas Board of Eclectic Examiners nor the Kansas City College of Medicine and Surgery could exist without the other. Arkansas, Florida and Connecticut, meanwhile, are three states which still have separate sectarian boards.

LICENSING OSTEOPATHS

During the last three years a few boards have examined osteopaths and licensed them as physicians. The objection to this is not that these candidates were osteopaths, but that their educational qualifications were seriously inferior to those which physicians are required to possess. Osteopathic colleges have been repeatedly inspected and, when measured by the same standards as are applied in the grading of medical schools, no one of them could rank higher than the lowest Class C medical college. Nevertheless, fourteen osteopaths were licensed as physicians in Colorado by examination, thirteen in California, two in Washington, and one each in New Hampshire and Texas.

THE STATISTICS

Special attention is called to Table I (page 1097), which shows the states—Illinois leading—which are registering the largest numbers of graduates of Class C and Class B colleges. Other states in this group are Arkansas, California, Colorado, Tennessee, Nebraska and Texas. The figures in Table H (page 1096) indicate that applicants are flocking to states—Massachusetts, for example—in which adequate educational safeguards have not been provided.

The effect of these statistics on both medical education and medical licensure has been profound. The first step toward the securing of improvements in any reform is to find out where improvements are needed. That has been the function of these statistics in medical education and licensure.

When the collection of data from the various boards was begun by THE JOURNAL in 1903, reports from many states could not be obtained for the very reason that records were not complete or were too imperfect to enable the boards to supply the information needed. That this condition has been corrected is evidenced by the fact that for the last several years full and complete reports have been received from all state boards.

Since 1905, the collection of these statistics has been an important part of the work of the Council on Medical Education in its campaign for the improvement of medical education and licensure. The effectiveness of publicity in medical licensure may be noted in Table M, on page 1099. Higher standards of preliminary education have been adopted; all states now require

that applicants must have graduated from a medical school; all but one state, New Mexico, now require an examination of all applicants; a larger number of states have improved their examination by the use of practical laboratory and clinical tests; a larger number of states have obtained authority to refuse recognition to low-grade medical colleges and are making use of that authority; reciprocal relations between states have been widely extended; ten states require a hospital internship as an essential for the license, and all but a few states now have single boards of medical examiners.

EFFECTS ON MEDICAL EDUCATION

On medical education the effect of these statistics has been even more pronounced. Publicity regarding the percentages of failures of graduates at state licensing examinations has led to the adoption of better methods of teaching. Publicity of the fact that in certain states diplomas granted by various colleges were not recognized as an acceptable qualification for the license induced a number of medical schools to make improvements in order to retain students. That such improvements have been made is shown by the increased number of colleges each year which are recognized in all states.

Briefly, these statistics show each medical school what improvements are essential if its graduates are to succeed in examinations of state boards; what state boards are requiring as a minimum of preliminary education, and in what states the boards are refusing to examine its graduates. To each state board these statistics show, by comparison with other states, the lines along which further improvements are needed in its educational standards and methods of examination. Constant publicity has led to a general improvement and a greater uniformity in the methods of examination by all state boards. The result has been a lessened confusion in the licensing of physicians throughout the country, and correspondingly better safeguards for the public against the licensing of incompetent practitioners.

ACCURACY OF THE WASSERMANN TEST

Under the auspices of the Medical Research Committee, established under the British National Health Insurance Act, numerous investigations have been made of scientific problems affecting the health and the life of the people. Already more than fifty special reports have been issued. The committee considered that the national and racial importance, no less than the scientific interest of the problems relating to syphilis, were a matter for early investigation, and several reports have been issued in this connection. In a previous report¹ of the Special Committee

on Pathologic Methods, the diagnostic value of the Wassermann test was considered. The clinical opinion of a well-known syphilologist was compared in a given set of cases with the results obtained by the Wassermann reaction as performed by four expert serologists working independently. The results were found to be in the closest accordance with the clinical opinion.

In a recent report² the investigation has been carried further: the Wassermann test during life was correlated with the etiologic or anatomic diagnosis made during life and after death. The first part, by Dr. Hubert M. Turnbull of the Pathologic Institute of the London Hospital, concerns the accuracy of Wassermann tests applied before death as related to the findings on postmortem examinations. It is stated in the introduction that whereas this test has been applied in millions of instances, "it is difficult, if not impossible, to find in medical literature a large series of cases in which the etiologic and anatomic diagnosis has been registered in addition to the clinical diagnosis." Dr. Turnbull's report deals with 121 cases in which Wassermann tests had been performed during life by Drs. Fildes and McIntosh. Following the deaths of the patients, minute examination of necropsy material was made. In many instances such minute examination is not made, with the result that lesions are overlooked. It is possible, for instance, that a Wassermann reaction may be positive and no syphilitic lesion may be found postmortem. This is possible because the lesion may exist and not be found; or because a lesion which was present has disappeared under treatment. On the other hand, a Wassermann reaction may be negative, and yet lesions believed to be syphilitic may be demonstrable.

As a result of his investigations, which included the making of thousands of microscopic sections, with their examination, interpretation and classification, Dr. Turnbull concludes that the Wassermann test performed antemortem, as was done in the 121 cases which he examined, is a diagnostic measure of astonishing precision. No proof of inaccuracy of the Wassermann test was found in the whole 121 cases, provided that the test is expected only (1) to give a positive reaction when syphilitic infection is active, and (2) to give a positive reaction either in the serum or in the cerebrospinal fluid when active syphilitic infection is confined to the central nervous system. The report is detailed, extensive, and apparently minutely accurate. It constitutes, therefore, an important document in the study of syphilis.

In the references to literature cited by the author, there is no reference to other than British, German and French periodicals. It would interest him, therefore, to refer to a paper on the value of the Wassermann reaction as indicated by postmortem investiga-

1. The Diagnostic Value of the Wassermann Test, Reports of the Special Committee on Pathologic Methods, Special Report Series 21, Medical Research Committee, National Health Insurance, H. M. Stationery Office, London.

2. Turnbull, H. M.: The Accuracy of Wassermann Tests, Applied Before and After Death, Estimated by Necropsies, Special Report Series 47, Medical Research Committee, National Health Insurance, H. M. Stationery Office, London.

tion in 331 cases at Bellevue Hospital, as reported by Symmers and others in *THE JOURNAL*.³ This paper, published in 1918, antedated even the beginning of Turnbull's work. Symmers, too, points out that certain anatomic changes in persons suspected of syphilis are sometimes exceedingly difficult to interpret, not only in the gross organs as they come under orderly examination at necropsy, but also in the subsequent microscopic investigation of individual tissues. He feels, however, that the errors in diagnosis for or against syphilis will balance. As a result of his investigation, he reports that the Wassermann reaction in the living patient gives a negative result in from 31 to 56 per cent. of cases in which the characteristic anatomic signs of syphilis are demonstrable at necropsy, and that it is positive in at least 30 per cent. of cases in which it is not possible to demonstrate at all the anatomic lesions of syphilis at necropsy.

Here, then, is a wide divergence of opinion, based in each instance on an apparently accurate scientific investigation. The subject obviously is susceptible to further study.

CALCIUM IN THE BODY

Calcium, which makes up about one fiftieth of the weight, constitutes a larger proportion of the body than is represented by any other of the inorganic elements. This fact is by itself sufficient to lend importance to all considerations of the supply of calcium to the body. It happens that this element is distributed with considerable irregularity among the staple articles of food, so that its intake depends in no small degree on the qualitative character of the diet. Among animal foods, milk stands almost alone in exhibiting a conspicuous content of calcium, while among plant products few show even moderate richness in this element. Such facts are probably responsible for the significant statement that "the ordinary mixed diet of Americans and Europeans, at least among dwellers in cities and towns, is probably more often deficient in calcium than in any other chemical element."⁴

In view of the widespread shortage of milk—"the calcium food"—in certain parts of the world, with a reduction in the use of milk following the higher price of this food in many places, the calcium problem in nutrition has become accentuated to an unusual degree. The practice of adding green vegetables, comparatively rich in calcium, to the dietary of infants has increased in recent years. Students of the subject have expressed the belief that the value of such feeding lies in the effect on the mineral metabolism of the organism.⁵ They have reported that in children showing a delayed development, improvement has been brought about by

such additions, and they conclude, on the basis of the mineral content of a number of vegetables, that spinach is the best one to provide a salt addition.

From experiments on animals, McClugage and Mendel⁶ of Yale University gained the impression, through a study of carrots and spinach, respectively, as substitutes for milk in furnishing calcium in the dietary, that their use does not always yield a pronounced advantage to the calcium metabolism. Presumably, therefore, it would be an unsafe procedure to use vegetables extensively as a dietary substitute for milk in the nutrition of children. That broad generalizations applicable to all species and ages are not yet justified, however, is indicated by more recent observations in the Department of Nutrition at Teachers College, Columbia University. Rose⁷ has ascertained the utilization of the calcium of carrots in the human body on persons for whom the calcium intake was in every case close to the estimated minimum for equilibrium. In almost every case there was a positive calcium balance on the carrot diet. When approximately 55 per cent. of the calcium was derived from carrots, one subject had practically the same retention as on a diet in which 70 per cent. of the calcium was derived from milk. Hence Rose properly argues that it seems possible to meet the requirement of the adult human organism for calcium largely, if not wholly, from carrots.

Another question, involving somewhat differently the content of calcium in the daily intake, relates to the possibility of increasing the content of this element in the blood by increasing the ingestion of calcium. This end is sought frequently in current therapeutic efforts, and calcium salts (chlorid, lactate, glycerophosphate) are often prescribed. The latest studies by Denis and Minot⁸ at the Massachusetts General Hospital indicate that it is difficult, if not actually impossible, to enrich human blood in this way. Even 6 gm. (90 grains) of calcium lactate administered orally each day for five days failed to alter the plasma content appreciably. It is possible, judging by the outcome of a few animal tests, that when the initial concentration is very low the amount in the circulating fluid may be more decidedly increased. This needs eventually to be determined in suitable human cases.

Current Comment

NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners up to December, 1919, had been in existence for four years,¹ and in that time had held seven examinations and examined 161 candidates, of whom 138 passed and received the board's certificate. A sufficient number of examinations have been held, and the board has been in existence long enough to permit its policies and methods to become fairly well established. It is now generally well known that the board has held to reasonably high educational standards, and that its examinations have been comprehensive, practical and thorough. The examinations have been such as to bring out the character of the applicant's medical training and to test not only his ability to memorize, but also his power to observe and his ability in reaching accurate diagnoses to apply the knowledge he has obtained. That the methods and the character of the examinations of this board are being appreciated is evidenced by the fact that twenty state boards² are now recognizing its certificates. The expenses of the board have been approximately \$15,000 each year, the funds having been provided by the Carnegie Foundation for the Advancement of Teaching. This is a large expense, in view of the small number of candidates examined. That the board has not made more rapid advancement and performed a larger function is due mainly to its failure to conduct its examinations in a larger number of cities. It would appear that arrangements could be made so that the written portion of the examination might be held simultaneously in all parts of the country, as is that of the College Entrance Examination Board. It might at least be held in the various cities where medical schools are located. The manner by which the applicants could be given their practical, laboratory and clinical tests could doubtless also be worked out. It would appear that the work and influence of this board could be many times greater than it is at present, and its service to humanity correspondingly increased. The possibilities of this board for good are tremendous; but it is not making the most of its opportunity.

MULTIPLE BOARDS AND CONFUSION IN LICENSURE

The chief difficulty in medical licensure at present is the confusion caused in several states by the multiplicity of the medical and sectarian boards which have to do with the licensing of those who are to treat the sick. This condition should be corrected. Whether or not the practitioner is to make use of medicinal substances, whether he is to apply massage, electricity, cold compresses or to perform a surgical operation is not so material. The matter of first importance is whether he who holds himself out to treat the sick has had training sufficient to familiarize himself not only with the normal conditions and functions of the

human body, but also with the various forms of disease so that he may tell whether or not a patient is sick, and if so, what the trouble is. The practitioner should also be familiar with the many procedures and materials used in the treatment of human disorders so that he can select and apply the right treatment to each particular patient. These statements apply to all practitioners of the healing art regardless of the particular system or method of treatment they advocate. To claim that one form of treatment is applicable to all human disorders is as illogical as to state that the slide-trombone constitutes an entire orchestra. Before one specializes in the playing of any particular musical instrument in an orchestra he must first have secured a training in the fundamentals of music, so that he may know not only when to play but—fully as important—when he should not play. In fact, a note from an instrument in the wrong place may produce more disastrous results than if the player fails to respond at the time his part is indicated. So in the practice of the healing art. Every one who treats human disorders by any special method or system of treatment should first have a thorough training in the fundamental medical sciences, so that he will understand not only when his particular method should be used, but, even more important, when it should not be used. Here again, the use of the wrong method of treatment may produce results fully as disastrous, if not more so, than if such treatment is not used in cases in which it is indicated. In fairness to all who practice the healing art, therefore, there should be in every state: (a) one board of registration; (b) one standard of educational qualifications, and (c) one examination, including written, practical, laboratory and clinical tests. In other words, let all practitioners alike be required to possess reasonably high educational qualifications, and then let them practice as their educated common sense may dictate. Such a provision would not only end the confusion which exists in many states, but also insure better care for the public when sick or injured.

DOES PROHIBITION PAY FROM A HEALTH STANDPOINT?

With the beginning of prohibition, alarmists—there are always such—predicted dire calamities: increase in crime, resort to habit-forming drugs and other vicious practices. The time has been brief for the compilation of accurate statistics on the subject, but some actual evidence has accumulated: In New York City, the Board of Ambulance Service has reported a large decrease in cases of alcoholism and intoxication. In 1919, during January and February, there were 412 and 364 alcoholic calls, respectively. This year, during the same months, these calls numbered 307 and 133. Bellevue Hospital's figures show 228 calls for intoxication during the first two months of 1919 and thirty-one calls for January and February of 1920. As a result, it is estimated that there will be room for seven thousand new patients a year in Bellevue Hospital, owing to the reduction in the number of alcoholic patients. These figures are for New York. What of other cities?

1. See statistics on page 1100, this issue.

2. The list is given on page 1100, this issue.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Personal.—Dr. John C. Davis, Harrisburg, has been appointed health officer of Poinsett County succeeding Dr. Robert E. Yarbrough, deceased.—Dr. Oliver H. Tatum has been appointed city health officer of Arkadelphia, succeeding Dr. William T. Rowland, resigned.

New Officers for State Board of Health.—At the annual meeting of the Arkansas State Board of Health, March 25, Dr. Cyrus F. Crosby, Heber Springs, was elected president, and Dr. Fergus O. Mahony, Eldorado, vice president, each for a term of one year, and Dr. Charles W. Garrison, Little Rock, was reelected secretary and state health officer for a term of four years.

New Society Organization.—At a meeting of the physicians of Little Rock, March 9, the North Little Rock Medical Society was organized. Dr. Shelby Atkinson, Argenta, was elected president; Dr. Martin J. Barlow, Argenta, secretary-treasurer, and a committee was appointed to confer with the finance committee of the city council on the erection of a hospital for North Little Rock.

Conference of Health Officers.—The seventh annual conference of health officers of Arkansas was held in Little Rock, March 25, under the chairmanship of Dr. Charles W. Garrison, Little Rock, secretary of the state board of health. The chief papers presented were by Dr. Charles W. Goodard, Austin, state health officer of Texas, on "The Way We Do Things in Texas"; by Miss Lillie Beauchamp, state supervisor of the American Red Cross, on "The Necessity of State Supervision of Public Health Nurses," and by Miss Earl Chambers, executive secretary of the Arkansas Public Health Association, on "How the Arkansas Public Health Association Can Assist Health Authorities."

DISTRICT OF COLUMBIA

Construction of Gallinger Municipal Hospital Postponed.—The committee on the District of Columbia of the House of Representatives recently recommended the appropriation of \$1,500,000 for building the Gallinger Municipal Hospital in Washington. This appropriation was stricken from the District bill on the floor of the House following a debate showing that this appropriation was three times as large as that provided for exactly the same character of building in 1917. The District commissioners have been unable to negotiate a contract for the construction of the building since 1917 and members of Congress determined to postpone construction of this hospital indefinitely because of the excessive cost of construction at the present time.

GEORGIA

Personal.—A department of sanitary engineering has been established by the state board of health with Mr. H. C. Woodfall as state sanitary engineer. Mr. Woodfall was formerly assistant sanitary engineer with the U. S. Public Health Service, and will devote his time to problems of water supplies, sewage disposal and drainage for the state.—Dr. Frank W. McCorkle, former assistant health officer of Madison County, Ala., has been elected commissioner of health of Decatur County.

Venereal Disease Control.—The venereal disease control work has been keeping pace with its program in the state very well. The interest in the county unit plan has been intensified, and the representatives of the state board of health in their respective counties are doing good work. The department of venereal disease control has mailed to the physicians a supply of report blanks in the past few weeks. It is hoped that physicians will be prompt in making reports. The law is given on the cover of the book of forms, and it is believed that reports on venereal diseases will soon reach a satisfactory basis.

ILLINOIS

Physicians' Licenses Revoked.—At its meeting, April 1, 1920, the Illinois Department of Registration and Education

revoked the licenses of Dr. George W. Alverson, formerly of Area, and Dr. Henri E. R. Altenloh of Chicago. The former is now serving a life sentence in the Joliet penitentiary and his license was revoked for gross unprofessional and dishonorable conduct. The license of Dr. Altenloh was revoked because of the use of alleged false and fraudulent statements in advertising matter by which he attempted to obtain money and practice.

Chicago

Personal.—Dr. Myron E. Lane, at present a member of the staff of the Chicago Municipal Tuberculosis Hospital, has been appointed medical director and superintendent of the Jasper County Tuberculosis Sanatorium, Webb City, Mo.

Industrial Surgeons' Association.—The organization of an Industrial Surgeons' Association to be affiliated with the Chicago Medical Society is contemplated. Dr. George D. J. Griffin is temporary chairman, and Dr. Horace C. Lyman, temporary secretary of the new organization.

Tuberculosis Society Meeting.—The thirty-ninth meeting of the Robert Koch Society for the Study of Tuberculosis will be held at the City Club, April 19, at 8 o'clock, when Dr. Lawrason Brown of the Trudeau Sanatorium, Saranac Lake, N. Y., will read a paper on "The Diagnosis of Intestinal Tuberculosis." A dinner will be given Dr. Brown at 6:30, at the City Club.

Institute of Medicine.—At the meeting of the Institute of Medicine of Chicago, April 16, at the City Club, Prof. R. A. Millikan, professor of physics at the University of Chicago, one of the most active experimentalists in the field of electron research and vice chairman of the National Research Council during the World War, presented a paper on "Twentieth Century Contributions to Our Knowledge of the Atom."—From a source that for the present must remain unknown, the sum of \$250 annually has been offered to the Institute of Medicine of Chicago for an annual lecture to be known as the Pasteur Lecture.

Joint Meetings.—The Chicago Medical and the Chicago Urological societies, met in joint session April 14, when papers were presented by Dr. Irvin S. Koll on "Urinary Calculi"; by Dr. Robert H. Herbst and Alvin Thompson on "Vasotomy," a lantern slide demonstration of technic; by Dr. Louis E. Schmidt, on "Streptococcus Infection in Urology"; and by Drs. Gustav Kolischer and Joseph Eisenstaedt on "Unilateral Nephritis."—A joint meeting of the Chicago Neurological and Chicago Pathological societies was held April 12 at which Dr. Fred T. Rogers of the University of Chicago presented a paper on "The Relations Between Arterial Blood Pressure, Heat Regulation and the Cerebral Hemisphere"; Dr. G. W. Bartelmez of the University of Chicago, one on "The Morphology of the Synapse in Vertebrates," and Dr. S. Walter Ranson of Northwestern University Medical School, one on "Studies on the Sympathetic Nervous System."

INDIANA

Personal.—At the annual banquet of the Military Order of Foreign Wars held in Indianapolis, April 6, Col. Carleton B. McCulloch was elected surgeon, Lieut. Morris G. Fuller, secretary; the latter succeeds Major Frank W. Foxworthy, resigned after fifteen years' service.

New Building for Sanatorium.—Sunnyside, the Marion County institution for the treatment of tuberculosis, located near Indianapolis, has been given \$350,000 by the county council to be used in the construction of new buildings. An infirmary with a capacity of seventy-five patients, a children's cottage of a forty-five bed capacity, and a superintendent's residence will be built. Work is to begin at once. Several months ago \$100,000 was appropriated for a service building and a power house, and these buildings are now nearing completion.

Epileptics in Indiana.—The board of state charities reports that there are at present 1,020 epileptics in the various public institutions of the state: in the five state hospitals for the insane, 266; schools for feeble-minded youth, 212; village for epileptics, 371, and in county poor asylums, 171. Of the total number, 366 are insane, 548 feeble-minded and 106 without marked mental deficiency. Men and boys number 602, and women and girls, 418. The epileptics are thus classified by ages: under 16 years old, 72; from 16 to 45, 617, and over 45 years, 331. Eighty-five of the ninety-two counties are represented at the village for epileptics. According to estimates there are 4,123 epileptics in Indiana, and of this number about 25 per cent. are receiving proper care from the state.

MAINE

Health Union Organized.—The first health union to be formed in the state has just been organized by the towns of Milford, Old Town, Bradley, Orono and Veazie under the name of the Mothov Health Union. A committee of six, two from Old Town and one from each of the other towns, conducts the affairs of the union, and a full-time health officer has been appointed. The organization of this health union is unique in Maine health history, for though such cities as Portland, Lewiston, Auburn and Bath employ full-time health officers, and the little town of York, unassisted except by the state appropriation of \$800 also supports a full-time officer, no attempt has previously been made to create a union of towns.

MASSACHUSETTS

Course in Early Diagnosis of Tuberculosis.—A course in the early diagnosis of pulmonary tuberculosis and methods of treatment will be given under the auspices of the Wachusett Medical Improvement Society at the Rutland State Sanatorium. Lectures will begin Thursday, May 20, and continue Thursday of each week until June 24. Those giving lectures include Drs. George N. Lapham, Rutland; Bayard T. Crane, Rutland, and these members of the sanatorium staff: Drs. Ernest B. Emerson, Rutland, superintendent; Leon A. Alley, Rutland, assistant superintendent; David E. Mann, Rutland; Halbert C. Hubbard, Auburn; William B. Davidson, Pawtucket, R. I., and Mary E. Gaffney, Providence, R. I. The object is to promote early diagnosis and control of pulmonary cases. The course will be open to all physicians. The facilities at Rutland are ample for illustrating any phase of the subject. There will be no charge for tuition. For further information address Dr. Ransom A. Race, secretary, Paxton, Mass.

MICHIGAN

Personal.—Dr. Don M. Griswold, Detroit, director of the medical service for the Detroit City Board of Health and professor of hygiene and preventive medicine at the Detroit College of Medicine and Surgery, has been appointed professor of hygiene and preventive medicine in the State University of Iowa, Iowa City, and state epidemiologist, succeeding Dr. Edward G. Birge, deceased.—At the last meeting of the Institute of Medicine of Chicago, Dr. Victor C. Vaughan, Ann Arbor, was elected an honorary fellow.

MISSISSIPPI

Murderer of Physician Sentenced.—A verdict of guilty as charged and carrying the death penalty was brought in by a jury, March 27, against Jesse S. Watts, charged with the murder of Dr. D. S. Alverson, Vicksburg.

State Gets Vicksburg Hospital.—The mayor of Vicksburg has been authorized to sign a resolution by which the Vicksburg Hospital may be conveyed to the state with the provision that when the state abandons the use of the property as a hospital the property shall revert to the city.

Women in Social Hygiene Campaign.—The United States Public Health Service cooperating with the state board of health has procured the services of Drs. Lenna L. Meanes, Des Moines, Iowa; Bessie Florence L. Meredith, Watertown, Mass.; Hannah Morris, West Chester, Pa., and Jeanette H. Sherman, Ridley Park, Pa., who have been employed by the U. S. C. A., and have had experience in social hygiene work in the eastern and central states. They will come to Mississippi for a series of lectures and conferences with the object of awakening the women and girls of the state to a realization of their responsibility and power for improving social conditions, and raising standards of health in their own communities, to put the facts before them and to help them to organize for definite action in fighting disease by advancing health through health education, and supervised recreation.

MISSOURI

New Officers.—Howard County Medical Society at its annual meeting held in Glasgow, March 19, elected the following officers: Dr. Elbert King, New Franklin, president; Dr. W. E. Williams, Fayette, and Walter M. Dickerson, Armstrong, vice presidents, and Dr. Charles W. Watts, Fayette, secretary-treasurer.

Personal.—Dr. Ross A. Woolsey, St. Louis, has been appointed chief surgeon for the St. Louis and San Francisco

system, succeeding Dr. George W. Cale, Jr., resigned. Dr. Woolsey has been first house surgeon for the Frisco system for the last eight years.—Dr. Karl E. Baker, Carthage, has been appointed state commissioner of health for Jasper County.

NEW JERSEY

Personal.—Dr. Marcus W. Newcomb, Brown's Mills, has been elected superintendent of the Burlington County Sanatorium for tuberculosis.

Newark Physicians Attack Volstead Act.—At a conference between the mayor and physicians of Newark, it was decided to oppose the Volstead act which limits the prescription of liquor in the treatment of illness.

Illegal Practitioners Prosecuted.—James Baker, Atlantic City, and Thomas G. DiSanti have been convicted under the New Jersey Medical Practice Act of practicing medicine without licenses. Each paid the penalty of \$200 and costs. —Minnie Usserow, Passaic, a licensed midwife, was found guilty of practicing medicine without a license and fined \$200 and costs.

Smallpox in Belleville.—On account of the prevalence of smallpox in Belleville, all churches, motion picture theaters, and places of public assembly were ordered closed. Up to the present time, there have been thirty-four cases of smallpox reported. Fifteen of the patients are in the County Isolation Hospital, Soho, and the remainder are under quarantine in their own homes.

Oppose Medical Bills.—Representatives of the Medical Society of the State of New Jersey met with the senate public health committee, March 22, to voice their protests against the new chiropractic law and the Hyland bill, which allows osteopaths to practice medicine and surgery without educational qualifications equivalent to those required of physicians, against the senate bill which provides for drugless therapists, and the bill which requires physicians to register annually. The physicians favor the senate bill to put all practitioners under the control of the State Board of Medical Examiners, and the certified milk bill, which will give the state control over certified milk for the use of children.

NEW YORK

After-Care Sanatorium for Poliomyelitis.—Public spirited people in Ithaca, Hornell, Corning, Cortland and Bath have taken action to secure quarters in Ithaca for a permanent sanatorium for the after-care of those who have had poliomyelitis.

Lake Keuka Physicians Meet.—The twenty-first annual meeting of the Lake Keuka Medical and Surgical Association will be held at Keuka College, Keuka Park, July 29 and 30, under the presidency of Dr. Alfred W. Armstrong, Canandaigua.

County Laboratory in Amsterdam City Hospital.—The Montgomery County Laboratory is to be established in the Amsterdam City Hospital. Alterations are being made in the hospital building for the purpose of providing suitable housing accommodations for this new laboratory.

Personal.—Dr. Fred M. Meader, director of the division of communicable diseases of the New York State Department of Health, has been granted an indefinite leave of absence in order to accept an appointment as surgeon in the U. S. Public Health Service. Before entering the service he will be associate in epidemiology in the School of Hygiene and Public Health, Johns Hopkins University, for the remainder of the collegiate year.—Dr. Ralph E. Robinson, Nunda, has been appointed to the state laboratory staff.

Protects Public Against Fake Remedies.—The village of Athens has incorporated into its sanitary code a regulation providing that no corporation, association, firm or individual other than licensed pharmacists and physicians shall sell or offer for sale in the village of Athens any medicine or so-called remedies, or any so-called medical appliances, unless before offering their commodities for sale they shall receive a permit from the local health officer. Any wilful violation of this regulation is punishable by a fine of \$50 for each offense.

Child Welfare Laws.—On the recommendation of the conference on child welfare held in Albany last October, a bill has been introduced in the state legislature proposing a commission for the codification and unification of the laws relat-

ing to the protection of children. The commission will investigate the operation and effect of all laws affecting children, ascertain any overlapping and duplication, and will recommend to the legislature such remedial legislation as may appear necessary for unification of the laws and concentration of agencies dealing with child welfare.

The Cotillo Bill.—Senator S. A. Cotillo has introduced a bill into the New York legislature regulating the prescription and sale of narcotic drugs. This bill is modeled on the federal law and does away with the necessity of becoming familiar with two sets of regulations. All the druggist has to do is to be familiar with the Harrison law and the Treasury regulations. The only exception is that the bill does provide for triplicate state order forms to be used in the purchase of narcotic drugs and regulations as to the use of these forms. These regulations will be printed on the back of these forms. The bill does away with special state requirements as to records and reports and with the special state registration of druggists, state certificates and state registration fees. The house of delegates of the Medical Society of the State of New York has approved the measure.

New York City

Personal.—Dr. Harry Plotz, Brooklyn, has been sent to Poland by the joint distribution committee of the American Jewish Relief Funds to combat the typhus plague there.—Dr. T. Mitchell Prudden has been reappointed a member of the public health council of the New York State Department of Health.

Convalescent Camps for Soldiers.—The New York Community Service announces that arrangements have been made for the establishment of summer camps at Bear Mountain and Fire Island for the benefit of convalescent service men and other former soldiers and sailors who are taking vocational training in New York City.

Many Vacancies in Health Department.—The work of the health department is said to be seriously crippled by the many resignations that have been handed in during the past six months. From July 1 to Dec. 1, 1919, there were 233 resignations, an average of one person a day. Most of these employees have resigned because they could command higher salaries elsewhere.

Organizations Unite to Fight Tuberculosis.—Various organizations in this city interested in fighting tuberculosis met at the New York Academy of Medicine, April 7, and decided to pool their intelligence, experience and equipment in order to carry on an intensive educational campaign against tuberculosis. They propose to make a survey of the city and establish auxiliaries in every existing clinic. Dr. T. L. Lloyd, vice chairman of the auxiliaries in the Brooklyn district, presided at the meeting. When the work of these various organizations is coordinated, duplication of effort will disappear and there will be a standardization of methods both in the handling of cases and in the after-care.

Formation of Caduceus Post of the American Legion.—On April 6 an amalgamation of the Medical Department Post of New York and of the Harry D. Gill Post of the American Legion took place in New York City. The great majority of the members are physicians. It has been decided to solicit other physicians to join this Post, either as regular or associate members (the latter applies to those who are active members of other posts). The following officers have been elected: president, Howard Fox; vice presidents, Harlow Brooks, George E. Maurer and Graeme M. Hammond; secretary, Samuel Bradbury; treasurer, William F. Cunningham, and county delegates, Harlow Brooks and Charles J. Imperatori.

NORTH CAROLINA

Failed to File Birth Certificate.—For failure to comply with provisions of the state vital statistics law by refusing to file birth certificates, Dr. Henderson Irwin, Eureka, is said to have been convicted in the local court of Fremont, March 15, on two counts and fined \$15 in addition to the costs of \$7.50.

Health Officers to Meet.—The tenth annual meeting of the North Carolina Health Officers Association will be held at Charlotte, April 19, jointly with the meetings of the state medical society and the state hospital association, under the presidency of Dr. Everett F. Long, Lexington, the subject of whose address will be "Coordination of Health Work—Intra-Governmental and Extra-Governmental."

State Medical Society Meeting.—The sixty-seventh annual meeting of the Medical Society of the State of North Caro-

lina will be held in Charlotte, April 19 and 20, under the presidency of Dr. Carl V. Reynolds, Asheville. Dr. Watson S. Rankin, Raleigh, will deliver an address on "State Medicine"; Dr. Benjamin S. Warren, Washington, D. C., will speak on "Social Insurance," and Dr. William L. Clark, Philadelphia, will give an illustrated lecture on the "Treatment of Malignant Disease."

OHIO

Lima Entertains Physicians.—Physicians within a radius of 50 miles of Lima attended the medical and surgical clinics held at St. Rita's Hospital, Lima, April 6. Dr. Dean D. Lewis, Chicago, spoke at the evening session.

Filtration Plants to Be Constructed.—It has been decided to build water filtration plants at Delaware, Greenfield, Eaton and Fremont. Plants at Shelby, Wadsworth and Ashland are nearing completion. Contracts will soon be completed at Delaware and Wauseon.

Collaborating Epidemiologists Appointed.—The U. S. Public Health Service has appointed 140 health commissioners of Ohio as assistant collaborating epidemiologists. This appointment gives them the privilege of using frank mail for their morbidity reports.

Personal.—Dr. Orrillus M. Corson, state Americanization director, Columbus, has resigned on account of ill health.—Dr. Albert H. Haworth, West Milton, has been appointed full-time health officer of Miami County, excepting the cities of Piqua and Troy.—Dr. Charles G. Augustus, health commissioner of Springfield for three years, has resigned.—Dr. Henry J. S. Dickson, Mechanicsburg, has been appointed full-time health commissioner of Champaign County.

Public Health Nurses.—There are at present 405 public health nurses that work in the state, not including nurses employed in industrial plants. This gives one public health nurse to every 14,320 population. Of the eighty-six counties of the state, thirty-three have, as yet, no nursing service. Twelve city and ten county boards of health now employ a total of seventeen nurses; city boards of education employ twelve, and one county board has a nurse. Altogether school boards are employing fifty-nine nurses.

SOUTH CAROLINA

New Medical Practice Act.—A new medical practice act was passed by the South Carolina legislature and was approved by the governor on March 10. The principal changes brought about by this act are: (a) The board is empowered to recognize certificates issued by the National Board of Medical Examiners. (b) The time fixed for the annual meeting of the board was changed from the second to the fourth Tuesday of June. (c) The registration fee was raised from \$10 to \$25. (d) It is clearly specified that practitioners of various forms of healing shall be required to take the same examination as regular physicians except in materia medica, major surgery, therapeutics and practice and must exhibit a diploma from a college approved by the board.

TEXAS

South Texas Physicians Meet.—The forty-seventh annual meeting of the South Texas District Medical Association was held in Beaumont, March 25 and 26, under the presidency of Dr. Claude C. Cody, Jr., Houston. Victoria was selected as the place for the fall meeting.

WISCONSIN

Personal.—Dr. Herbert G. Lampson, Washburn, superintendent of the Nopeming Sanatorium, Duluth, has been appointed county physician of St. Louis County.

Fire in Hospital.—Fire of unknown origin destroyed the hospital and home of Dr. Ernest G. Ovitz, at Laona, March 1. The patients were removed without casualty, and the loss is estimated at \$20,000, partially covered by insurance.

CANADA

Aesculapian Club Officers.—Dr. David J. Gibbs Wishart has been elected president of the Aesculapian Club, Toronto; Dr. Alexander Primrose, C.B., vice president; Dr. Edmund E. King, treasurer (reelected), and Dr. Frederick C. Harrison, secretary.

Liquor Prescriptions.—The chairman of the Board of License Commissioners of Ontario has informed a committee

of the legislature that 80 per cent. of Ontario physicians write less than ten prescriptions for liquor in a month, and that it is the balance of from 10 to 20 per cent. who are the "official bar-tenders" of the province. That would mean that the bulk of the liquor prescriptions is issued by from 350 to 700 men.

Druggists Protest.—Prohibitions in the bill to amend the Canadian opium and drug act now before the House of Commons brought to Ottawa a large delegation of druggists last week. They object to the provisions of the bill which prevent their selling certain mixtures containing small but necessary quantities of opium, morphin and other narcotics unless under a medical prescription. They seek an amendment so that they may sell cough mixtures, etc., as they have always done without doctors' prescriptions.

Hospital News.—At a meeting called by the Canadian National Committee on Mental Hygiene in Toronto a few days ago, resolutions were passed favoring the establishment of the proposed new Reception Hospital for Toronto, contiguous to the University of Toronto and the Toronto General Hospital. Last year fifty-four mental cases were sent to the hospital for the insane after passing through the hands of the police.—The establishment of a general hospital for the border towns near the Detroit River is being agitated. It is likely that it will be established at Windsor, Ont.

Personal.—Sir Thomas G. Roddick, Montreal, and wife have returned after spending the winter in Florida.—Dr. Newtown A. Powell, Toronto, is president, and Dr. John N. E. Brown, Toronto, is secretary of the Chengtu Medico-Dental College Project in Canada.—Dr. David Fuller McKinley, C. A. M. C., formerly of West China, has commenced practice in Toronto.—Dr. John L. Todd of McGill University, with Dr. Simeon B. Wolbach of Harvard Medical School, has gone to Poland to study typhus fever. They are working under the Red Cross.—A banquet was recently tendered to Dr. George A. J. Glionna, Italian consul in Toronto, for his patriotic work among Italians there during the war.—Dr. Charles J. Copp, Toronto, was recently presented with a gold watch and chain for his work in connection with the St. John Ambulance Brigade of which he is assistant commissioner in Toronto.—Dr. James Beatty, Toronto, has been appointed pathologist of the General Hospital, Regina, Saskatchewan.—Dr. Russell L. Parr, Toronto, formerly captain in the department of soldiers' civil reestablishment, accused of defrauding the Canadian government of \$2,500, has been acquitted.—Dr. Edgar C. Barnes, for fifteen years assistant medical superintendent at the Homewood Sanitarium, Guelph, Ont., has been appointed medical superintendent of the hospital for mental diseases at Selkirk, Man.

GENERAL

Medical Book Plates Wanted.—THE JOURNAL will be glad to receive copies of the book plates of physicians, for use in a review of the subject. Copies of the book plates of noted physicians, now dead, will be especially appreciated. Mark envelop "BOOK PLATE."

Gift to College of Surgeons.—The Carnegie Corporation has given to the American College of Surgeons \$75,000 to be used for hospital standardization. Four years ago, it made a gift of \$30,000 for the same purpose, making a total of \$105,000, this amount being supplemented by funds of the college.

Conference Regarding Service Men.—The committee representing welfare agencies for disabled former service men of Indiana, Kentucky and Ohio held a meeting in Indianapolis, April 10, at which Dr. Thomas B. Victor Keene, Indianapolis, chairman of the hospitalization committee, and Dr. Henry Kennon Dunham, Cincinnati, chairman of the education committee, made their reports.

Legislature to Permit Transmission Through Mails of Poisons.—The House of Representatives has passed the bill permitting the transmission of poisons, medical or chemical compositions, through the mails, under regulations prescribed by the Post Office Department. The bill permits manufacturers or dealers in such products to transmit them to licensed physicians, surgeons, pharmacists and druggists.

Gift to Post Graduate Hospital Endowment Fund.—The New York Post Graduate Medical School and Hospital reports a gift of \$100,000 from Mrs. Henry R. Rea of Pittsburgh toward the endowment fund of \$2,000,000 which the

institution is striving to raise. It is reported, also, that Mr. James C. Brady of New York has given \$50,000 toward the first million and has pledged \$125,000 toward the second million. Mr. Vincent Astor has given \$50,000 toward the first million and an additional \$75,000 toward the second million.

Examination for Canal Service Physician.—The United States Civil Service Commission announces an open competitive examination for physician, Panama Canal service, May 5 and July 7, at various places throughout the United States. The entrance salary is \$200 a month with promotion to \$300 or higher for special positions. Both men and women are eligible. They must be unmarried, must be graduates of a recognized medical school, and must have had at least one year's graduate hospital experience. Application should be made to the Civil Service Commissioner, Washington, D. C., or the secretary of the local United States Civil Service Board.

Centenary of Medical Missions.—The centenary of medical missions was celebrated generally throughout the United States from March 28 to 31, and at the same time observance was made of the fiftieth anniversary of the work of the first woman missionary. The pioneer medical missionary was Dr. John Scudder, who went to Ceylon in March, 1820, and the pioneer woman medical missionary was Dr. Clara Swain, who went to India in 1870. It was pointed out that forty-eight members of Dr. Scudder's family followed him into the mission field and that three of the fourth Scudder generation had just gone to begin their life work in India. At present there are about 1,100 medical missionaries working in 702 hospitals and 1,156 dispensaries.

Bequests and Donations.—The following bequests and donations have recently been announced:

Hospital for Sick Children, Toronto, Ont., \$1,000 to endow the McRoberts' cot, by the will of Mrs. Ruth McRoberts.

Philadelphia Orthopedic Hospital a bequest of \$5,000 from the residuary principal of the estate of Mrs. John M. Walton to establish a free bed in memory of her husband.

American Red Cross and St. Luke's Hospital, New York City, chief eventual legatees of the estate of James A. Scrymgeour, appraised at \$2,923,040 to become operative on the death of his widow.

Chengtu Medico-Dental College Project in Canada, \$7,500 by the will of Dr. Richard A. Reeve, Toronto.

St. Vincent's Hospital, New York City, \$100,000; Cancer Hospital, New York City; Industrial Home for the Blind, Brooklyn, and Brooklyn Hospital, each \$25,000; Brooklyn Home for Consumptives, \$20,000, by the will of Daniel G. Carroll.

FOREIGN

Medical Journal's Personally Conducted Tour to Paris.—A Spanish medical journal, the *España Médica* of Madrid, has organized a tourist party for its subscribers, with the collaboration of a tourist agency for the trip, and of the dean of the Paris Faculté de médecine for the scientific side of the trip. The expense for the twelve days is 750 pesetas. Three days are to be spent inspecting the devastated regions from Verdun to Reims. The journal states that if it were not for the prevailing rates of exchange the price of such a trip would be prohibitive at present.

Fourteenth French Medical Congress.—The Association of French-Speaking Physicians invites physicians to attend the Fourteenth Congrès français de médecine to open at Brussels, May 19, 1920. The first of the three topics to be discussed—syphilis of the cardiovascular apparatus—is to be presented by Bayet of Brussels, Etienne and Spillmann of Nancy, and Vaquez and Laubry of Paris. The second—lipoids in pathology—will be presented by Chauffard, Laroche and Grigaut of Paris, Linossier of Vichy, and Zunz of Brussels. The therapeutic value of artificial pneumothorax will be discussed by Burnand of Leysin, Küss of Agincourt, and others with much experience. The fee is 40 francs for non-members of the association.

Pan-Hellenic Congress of Hygiene.—The *Grèce médicale* announces that the long planned Congress for Hygiene and Demography is now organized to convene at Athens, April 25 to 30, 1921, the week of the celebration of the centennial of the independence of Greece. There are to be six sections, and membership is open to all interested in public and private hygiene, welfare work, and similar great social questions. The fee is 15 francs for regular members and 10 francs for associates. In connection with the congress there will be an international exhibition to remain open for two months. Prof. G. Phocas is chairman of the committee of organization of the congress, and the secretary is Prof. P. J. Rondopoulo, 14 rue Nikifouro, Athens, Greece.

Government Commissions in the Netherlands for Investigation of the Treatment of the Sick by the Unqualified.—THE JOURNAL described about a year ago the report of the medical commission appointed by the state in the Netherlands in 1915 to study the methods and practices of various cults. After exhaustive investigation the report presented concrete evidence that no essential benefit resulted from any of the methods and in some instances actual harm was done. A commission of eminent jurists was appointed at the same time. They have taken three years to prepare their report, and it has just been presented. The editor of the *Nederlandsch Tijdschrift voor Geneeskunde*, Prof. G. van Rijnberk, publishes their report with comment. The lawyers in their preamble state that their advice was asked only in the matter of suggesting modifications in the law, and not whether it is desirable to make such modifications. Consequently, they say, the report does not express any personal opinion of the jurists in this matter, but is restricted to the legal wording of the modifications to admit the unqualified to practice.

Friedmann in the Limelight Again.—The German medical journals for the last few months have been much exercised over the way in which the Kultusminister K. Haenisch (minister of public instruction), and the Prussian general assembly have been promoting Friedmann's "Preventive and Cure for Tuberculosis." Friedmann has been appointed professor extraordinary (without any consultation with the medical faculty), and part of a military hospital has been placed at his disposal for treatment of the tuberculous and to train students in the method. Nearly every German journal contains some report of experiences with the "Cure." Some of the writers complain that Friedmann insists on selecting the patients to be allowed the treatment, and refuses to let any other measures be applied with it. The *Nederlandsch Tijdschrift voor Geneeskunde* of Amsterdam quotes this same Minister Haenisch, speaking in the lower house two years ago, when he cited the Friedmann remedy as an example of "an arrant humbug which has the advantage that the inventor in the meanwhile has become a rich man." Our Netherlands exchange adds, "The psychanalysis of this change of view on the part of the minister of public instruction might be worth studying out." The *Deutsche medizinische Wochenschrift* for Dec. 18, 1919, referred to the matter as showing the lamentable way in which internal politics is encroaching on the domain of science, saying, "Even the sharpest critic of things as they used to be will have to admit, if he is truthful, that a minister of public instruction in former times would not have retained his position for one hour after delivering such a speech as Haenisch's recent speech, followed by the 'interview' in the evening paper (Haenisch and Friedmann's *Moniteur*)." It quotes further the *Medizinische Klinik* that it is "hard indeed that at a time when Germany is so impoverished in worldly goods, such action should threaten to lower the prestige of German science." The Prussian general assembly has recently voted to appoint a representative commission to test the remedy. It was said at first that no one who had previously tried the remedy should be on this commission but this principle was not adhered to. Twenty members were first appointed, mostly leading members of the profession, but others have been added later, including Friedmann himself, Prof. Kruse, who has charge of the bacteriologic control of the preparation of the remedy, Dührssen, an ardent advocate, and others. The *Deutsche medizinische Wochenschrift* comments that the handing over of the hospital to Friedmann and empowering him to train medical students in the method of treatment—before the commission has made any report on the value of the "cure"—"must be regarded as another one of the many inconsistencies from which the people is now suffering so much. . . . However, it was a favorable turn of fate that Friedmann did not succeed in his desire to have the Kaiser-Wilhelms-Akademie placed at his disposal, notwithstanding the efforts of Haenisch, Scheidemann and his other backers (gönner)." Another instance of what the *Deutsche medizinische Wochenschrift* calls the "hitherto unknown by-effects of a method of treatment," is a suit for damages brought by the editor of the *Münchener medizinische Wochenschrift* against another editor, Dr. Bachmann, of the *Biologische Medizin*, who had accused the former of "suppressing the free expression of opinion" by rejecting certain articles sent in for publication. The *Deutsche medizinische Wochenschrift* remarks that this lawsuit is a grateful opportunity to show the courts the absurdity of this complaint. The entire chorus of the "suppressed" will be presented to the judge.

LATIN AMERICA

Personal.—Dr. Rafael Otamendi of Caracas, Venezuela, has arrived in New York accompanied by his wife.—Dr. Rafael Medina y P., Quito, Ecuador, has arrived in New York on his way to France.

Experimental Hygiene at Montevideo.—The *Brazil Medico* states that the congress of Uruguay appropriated funds recently for the organization of an institute for experimental hygiene at Montevideo.

Plague at Curitiba.—Some dead rats having been found in a certain quarter of Curitiba, they were examined for plague bacilli with positive results, and the governor of the state telegraphed at once to the chief of the national public health service asking that a sanitary brigade be sent there at once before any clinical cases of plague develop.

Monument to Dr. Núñez.—The building of the monument to Dr. Enrique Núñez, former secretary of sanitation of Cuba, for which a fund of \$12,000 has been collected, will begin soon. The monument will be built at the entrance of the hospital, Calixto García, and it is expected that it will be unveiled on September 15, which is the fifth anniversary of Dr. Núñez' death.

American Physician Needed in Chihuahua.—Mr. Emmet W. White of the insular and foreign division of the American Red Cross has received a letter from the American consul at Chihuahua stating that the only foreign physicians in Chihuahua, one American and one Englishman, have died this year, and that there is an opportunity for an American physician, especially one who speaks Spanish. The American consul will be glad to correspond with any one who might consider locating there.

Riots Among Medical Students in Argentina.—The conflict between the professors and the students of the University of La Plata, reached its climax recently, when the medical students provided themselves with revolvers and opened fire on the school, killing one of the students, who was taking his examination at the time. A number of the students were arrested by the police. The University of La Plata is one of the three national universities, in addition to the two state colleges, and was the last organized of those existing in the country.

"Prophylaxia Rural."—This is the official name of the service that has been undertaken on a large scale in Brazil to carry the campaign against malaria, helminthiasis, etc., into the rural districts. The *Brazil Medico* is publishing the reports from different stations as they have been established. In one week recently, at one of these stations 1,284 persons were examined and 65.9 per cent. were found to have malaria or other chronic disease. At another station 94.11 per cent. were found infested with helminths and 1,186 persons were given treatment during January.

Deaths in the Profession.—Dr. L. R. Cassinelli, founder of the Cassinelli Sanatorium at Buenos Aires, and physician to the Hospital San Roque.—Dr. R. Leal de Sá Pareira of S. Paulo.—Dr. O. Vieira de Brito of Bello-Horizonte, president of the city council.—Dr. Rivadavia Correa, senator from his state, Rio Grande del Sul, and long leader in the movement for raising the standards and equipment of the medical schools of Brazil.—Dr. J. Maceo Chamorro, at Puerto Padre, where he was chief of the local public health service, one of the oldest physicians of Cuba.

Mexican Commission in the United States.—Drs. Edmundo Aragón, secretary of the Department of Health of Mexico, and Nicolás Amerena, director of the diagnostic laboratory of the same department, are being sent to the United States in order to secure cultures of plague, yellow fever, typhoid fever, cholera, pneumonia and all other infectious diseases, the etiologic agents of which are known. It seems that cultures of micro-organisms lose their virulence very soon in Mexico, and it is necessary to replace the supply quite often. While in the United States, Drs. Aragón and Amerena also intend to purchase a collection of wax models, showing different aspects of the most common diseases. They expect to visit New York, Washington, Chicago and New Orleans, inspecting at the latter city the methods of ship disinfection in force.

CORRECTION

Wrong Price Published in Advertisement of Oxford University Press.—In the advertisement of the Oxford University Press, published in THE JOURNAL for April 10, through an error, the Oxford Loose-Leaf Medicine was quoted at \$52.50. It should have read \$62.50.

Health Conditions of the Army

For the week ending April 2, progressive improvement in the health conditions among the troops is shown by the continued decrease in the admission and noneffective rates. There is a slight increase in the number of new cases of measles, scarlet fever, malaria, diphtheria and pneumonia, although none of these diseases are epidemic at any camp or station. As a whole, the report for the week shows the number of new cases of epidemic diseases to be about as low as could be expected. There were eighteen deaths from disease reported during the week: tuberculosis was reported to have caused seven and pneumonia four. Among the American forces in Germany the health conditions continue satisfactory.

Public Health Service Presents Building Requirements

The Public Health Service has presented to the Committee on Public Buildings and Grounds of the House of Representatives an analysis of prospective hospital building requirements for ex-service men. Twenty-five million dollars is asked for construction or purchase of necessary hospital buildings, \$15,000,000 of which shall be expended during the present year. These building requirements of the Public Health Service are based on the report of the chief medical adviser of the War Risk Insurance Bureau. This report indicates that the Public Health Service will be required to take care of 30,000 patients during the ensuing year. These patients are classified as: general, medical and surgical, 7,200; tuberculosis, 12,400, and neuropsychiatric, 11,000, a total of 30,600. The hospital building needs of the Public Health Service are most urgent, and the Committee on Public Buildings will at once determine the amount of money which will be appropriated for this work.

Army Hospital Internship

The Surgeon-General of the Army announces that internships of one year in some of the large general hospitals of the Army are opened to medical students and graduates of Class A medical schools who obtain a high standing and are indorsed by the medical school authorities. Satisfactory completion of the year in the Army General Hospital will be accepted as qualifying for commission in this regular Army Medical Corps without further professional examination.

The status of the intern is that of a civilian, and the pay is \$60 a month with quarters and rations.

The general hospitals of the Army are organized into three services: medical, including psychiatric and contagious diseases; surgical, including eye, ear, nose and throat, venereal, gynecologic, obstetric and the roentgen-ray service; laboratory, including clinical microscopy, pathology, serology, bacteriology and chemistry. Some of the medical schools requiring the fifth or hospital year for a diploma have already agreed to accept the hospital year in the Army general hospitals as the equivalent of their hospital year, and it is expected that state boards requiring hospital experience as a requisite for license will likewise accept that obtained in the Army. Applications for this internship should be made by letter direct to the Surgeon-General and give the following information: full name; present address; home address; birth place (if foreign, state whether a citizen of the United States); date of birth; education before entering medical school; medical school attended; date of graduation or prospective graduation, and statement of any physical defect that might disqualify applicant in physical examination.

A circular of information will be sent on application to the Surgeon-General's Office. A similar circular is in the possession of each state medical examining board.

Foreign Letters

BELGIUM

March 25, 1920.

The Medical Press

The great difficulties with which all Belgian industries are struggling seriously impede national reconstruction. The mining and metallurgic industries have been able to overcome obstacles which seemed insurmountable, despite repeated strikes, which were on the whole of short duration, and these industries are now again beginning to assume their customary place in the business world. The shortage of manual labor and the repeated strikes have not assumed such proportions that they would have proved fatal to the prosperity of Belgium. Strictly speaking, there is no prosperity in Belgium, but after the cataclysm which burst over the whole nation, one can be deemed fortunate to witness the present renaissance under conditions which can be considered favorable. This hopeful outlook does not altogether apply in regard to the medical press. In those countries in which scientific publications are not published directly through liberal subsidies from an official department, or where they are not equally as firmly established as in a great country like the United States, the shortage of necessities and the mounting cost of labor exert a very acute influence on the fortunes of scientific periodicals.

PRINTERS' STRIKE

A recent strike of the printers of Liège, which has just barely been settled, interrupted the publication of many periodicals for from three to four months. In the same way, the book industry has been seriously affected. If one adds to this the difficulty of procuring paper, one will readily understand that it is not always easy to guarantee uninterrupted appearance of many periodicals. Furthermore, new difficulties have lately surrounded the manufacture of paper. The decline of exchange does not permit Belgian printers to obtain the necessary supplies abroad, especially in Holland. In Germany, the exportation of wood and paper has been prohibited. France has smaller reserves than our own. Under these circumstances, we are obliged to be content with what little paper we manufacture. The supply does not equal the demand—far from it—and the costs of manufacture have increased almost tenfold as compared with prewar figures.

BIOLOGIC PUBLICATIONS

It is not surprising, therefore, that the purely scientific reviews appear at long intervals. The *Archives de biologie*, which publishes the more important works of the laboratories under the editorial supervision of Professor Brachet of the faculty of medicine of Brussels, is among those suspended for more than four months. The same is true of the *Archives de physiologie*, edited by Professor Fredericq of the faculty of medicine of Liège, which was affected by the same strike. The *Archives de pharmacodynamie*, under the editorship of Professor Heyman of the faculty of medicine of Ghent, has issued only two or three numbers since the armistice. The *Archives internationales de médecine légale*, founded by Professor Lorin of Liège—who died in March, 1919, leaving unfinished a whole series of excellent works—has not resumed publication.

The *Académie royale de médecine* alone continues, sometimes with considerable delay, publication of the reports which are deposited with its bureau and are accepted after examination. These must always be original contributions, as they deal almost exclusively with such phases of general biology as are not of direct interest to the medical practitioner. The latter has at his disposal the local weekly jour-

nals, publication of which has now become more regular. It should not be forgotten, moreover, that almost every physician subscribes for one of the large French weeklies, such as *Presse médicale*, *Paris médical*, and *Journal des praticiens*. Besides these reviews, which circulate through almost the whole of Belgium, as well as the Flemish section, there are many local journals

BELGIAN MEDICAL PUBLICATIONS

Le Scalpel is issued at Brussels. Before the war, *Le Scalpel et Liège médical*, combined, was published at Liège as a purely local review. At the beginning of 1919, the editorial staff was divided: some tried to give the journal a national character, and by shunning excessive provincialism they hoped to make *Le Scalpel* the official organ of the Belgian medical federation. This attempt was only partially successful, and *Le Scalpel* has become more especially a sectional organ for the central part of Belgium. Besides this, *Liège médical* has reappeared. Its debut was inauspicious, for the first number had hardly been issued when the strike interrupted publication for a considerable time. Despite the setback, however, its success seems assured, and several numbers which have since appeared are not lacking in interest. Both of these are weekly periodicals, devoted primarily to papers of immediate practical value, not long contributions, but mainly clinical notes and articles on general medicine. In addition, they frequently publish notes of interest to the medical profession, some society proceedings and medical news items.

Besides these two journals, the *Revue médicale de Louvain* remains the organ of the Catholic school. It has a purely didactic aim and continues to impart to the former pupils of the faculty the teachings which they received at their alma mater. It publishes, finally, the lectures of the professors of the faculty.

Ghent also has its medical bulletin, the *mémoires de la Société de médecine*, which records the papers and discussions of this society.

The *Archives médicales belges* is one of the most important medical journals of Belgium. Before the war, it was issued in a smaller format. The war, which had interrupted its publication, was instrumental in its revival at the battle front itself, where, after Jan. 1, 1917, there were brought together the most diverse collaborations of the Belgian medical world. Those who had gone with the army and those who rejoined it on the Yser continued to demonstrate, even through the hard years of exile, the vitality of Belgian medical science. Thanks to this continued effort throughout the war, the *Archives médicales belges*, at the time of the homecoming, was able to expand its editorial committee to include all the authorities of the four medical faculties, officers of the army medical corps, and the principal medical practitioners of Belgium. Appearing in monthly issues, it publishes original articles in all branches of medicine; each month there is a review of some general question, carefully summarizing current knowledge with bibliographic references. Under the heading "Analyses" are found many abstracts of the foreign literature. These are not arranged according to the journal in which the articles appear; each branch of medicine and each specialty are represented, and for every one of these the principal publications of the month are abstracted by a specialist. Under another heading are items of current interest and proceedings of scientific societies.

Among special journals, the *Journal de chirurgie* should be mentioned; in it are published the discussions of the Société de chirurgie de Belgique.

In a small country such as Belgium, it should be of great advantage, especially under the difficult circumstances at the present moment, to correlate all these endeavors now some-

what dispersed. There can be no question of the advisability of such a movement. But it seems that the smaller the country, the more is sectionalism carried to excess. In such a large country as the United States, where, despite diverse origins and customs, federated states have combined, this centralization has been successful—truly an interesting paradox.

BUENOS AIRES

Feb. 21, 1920.

Feeding of the Argentine Field Army

It is well known that the traditional diet of the country regions of Argentina is chiefly meat, although this custom has been considerably modified in the most populated districts. In the case of Argentine troops in the field, the medical officer, Dr. J. A. López, has made recent observations in Chaco, which indicate that the soldiers receive daily 435 grams of protein, 182 grams of fat, and 201 grams of carbohydrates, making a total of 4,125 calories.

Plague Considered an Industrial Accident

Two recent decisions by different courts have established the principle that plague contracted in a plant in which rat mortality from plague should create suspicions as to its sanitary conditions, makes the employer liable to pay a compensation just as if the patient had died from an accident while at work.

Campaign Against Malaria

The National Department of Public Health is oiling on a large scale mosquito breeding places in the departments of Famaillá and Trancas of the province of Tucumán. In the same zones and also in San Pedro and Río Chico in the province of Jujuy the department is carrying out drainage measures.

Maritime Quarantine

The insanitary conditions of almost all the ships arriving from Europe cause their detention in the port of Rio de Janeiro in order to isolate the sick and disinfect the ships. Some steamship companies have complained of this practice, as they consider as too long the periods of seven to fifteen days during which some boats have been delayed.

PARIS

March 11, 1920.

A Special Day in Aid of Large Families

On the initiative of the societies and leagues that are working to increase the birth rate in France, a special day, March 9, has been set apart on which to solicit contributions. The proceeds of the day will be distributed throughout France among such large-sized families as the most in need of assistance.

Death of Prof. G. Rauzier

Dr. G. Rauzier, professor of clinical medicine on the Montpellier Faculty of Medicine, died recently at the age of 56. He became agrégé professor in 1892, and in 1907 he was appointed professor of general pathology and therapeutics. Two years later he exchanged positions with his former teacher, Professor Grasset, becoming thus professor of clinical medicine. The last edition of the Grasset treatise on the diseases of the nervous system was put out by Grasset and Rauzier working in collaboration. In 1909, a treatise on the diseases of the aged, of which Rauzier was the independent author, was published.

The Influence of Sex on Pathology of Children

Dr. Apert, physician to the hospitals of Paris, recently published, in collaboration with M. Cumbessédès and M.

Flipo, an interesting communication on the subject of the influence of sex on the pathology of children. Aside from congenital luxation of the hip and chorea the influence of sex on the pathology of children is not marked. However, the greater frequency and the greater severity of influenza that had already been noted in young women and in women of mature age applies to young girls as well. For example, for the age group 2-9 the mortality from influenza in Paris was one and a half times as great for girls as for boys. In girls the fever is more prolonged and the complications more serious and more frequent, with the exception of epistaxis. The same is true for pertussis. Nearly all other diseases, however, show a slight excess of mortality for boys. From these facts Apert concludes that not only in matters of home training and general education but also as regards hygiene and therapeutics it is a serious error to fail to differentiate the two sexes.

The Physician as a Public Official

A medical inspector of infants and children who were the recipients of state charity, having been recalled by the prefects of three departments in which he exercised his functions, appealed to the Conseil d'état, which supported him in his contention. The Conseil d'état ruled that a physician in charge of the inspection of infants and children who were the recipients of state charity could not be considered a private physician; he represents the power of the state, and in that capacity it was his duty to see that the nurse fulfilled all the conditions required. In his official visits he represents the prefect, and, as a man of skill, it is for him to say how an infant shall be nourished. He is consequently a mandatory of the state and therefore a state official. As such he cannot be relieved of his official duties without first being informed of the act that is being contemplated, and thus be given the opportunity to demand a written copy of the charges preferred against him and to prepare and present his means of defense.

As for the physician in charge of the services in which free medical assistance is given, the situation is quite different. He is there giving medical care and is bound to his patient by the right of privileged communication. Under such circumstances the practicing physician would not be considered a state official. He is simply giving medical attention to a class of patients, in accordance with certain regulations and a special price schedule. The state in this case merely provides the medical care, and is in the same capacity as a mutual aid society or an accident insurance company.

LONDON

March 20, 1920.

Graduate Medical Education for Panel Physicians

The London Panel Committee has pointed out the necessity for the graduate education of panel physicians and the boundless opportunities afforded by the general and special hospitals of the metropolis. They suggest organization of special courses in such subjects as clinical diagnosis and treatment, radiography, tuberculosis, venereal diseases, disorders of digestion, ophthalmology, war neuroses and vaccine and serum therapy. In the months from May to September, when physicians have most time to spare, classes might be held in the evening after office hours. Classes of from twenty to twenty-five would be large enough for each member to receive some individual attention in any discussion that might and should take place after each lecture or demonstration. A course should number from eight to twelve lectures, including demonstrations. A fee of \$15 would be a reasonable one for each member to pay. The value of the system is obvious if only from the point of view of individual efficiency, but there is another point—the collective

efficiency of the insurance service. Changes involving the inclusion of the dependents of the present insured population are imminent. These will necessitate the physician's assuming greater responsibilities. It is hoped that in every district there may be physicians who by taking the necessary steps will become qualified to undertake some of the duties involved in one specialty or another. Classes have already been held at the Military Hospital, Rochester Row, in the diagnosis and treatment of venereal disease, and certificates signed by Lieutenant-Colonel Harrison have been issued to those considered expert in the administration of arsphenamin and similar drugs. To the holders of these, the public authorities are empowered to supply the drugs in question. It is proposed that attendance at the proposed courses shall entitle physicians to similar recognition.

The Nation's Physique

One of the results of the war is to furnish the only survey of the physical fitness of the male population of military age in this country ever made. It has now been presented to Parliament in an elaborate report by the National Service Medical Boards. The number of medical examinations during the period under review was 2,425,184, but this figure does not represent the number of men examined, as it includes reexaminations. Those examined were classed into four grades: Grade 1. Those who had attained the full normal standard of health and strength and were adjudged capable of enduring physical exertion suitable to their age. They amounted to 36 per cent. of the total. Grade 2. Those capable of only such exertion as does not involve severe strain. They amounted to 22 per cent. Grade 3. Those presenting marked disabilities or such evidence of past disease that they were not considered fit to undergo the physical exertion required for the higher grades. They amounted to 31 per cent. Grade 4. Those totally and permanently unfit for any form of military service. They amounted to 10 per cent. There are no figures to show how far this grading proved correct in the actual conditions of military service. But it can be stated that more recruits were degraded than upgraded. The figures, therefore, err on the side of overrating rather than underrating. An analysis of examinations of different groups of men between 18 and 25 years of age in one large and important district (Yorkshire) made with a view to revealing the influence of occupation on health gave the following remarkable results:

Occupations	Percentages			
	Grade 1	Grade 2	Grade 3	Grade 4
Agriculturists	71.9	15.5	8.8	3.8
Miners	68.9	15.1	10.5	5.5
Engineers	60.9	23.9	13.4	1.8
Iron and steel workers....	60.2	25.6	11.2	3.0
Lace workers	45.0	26.9	22.7	5.4
Woolen trade	54.6	10.9	24.0	10.5
Tailors	33.9	21.4	33.5	11.2

It will be noticed that the miners and agriculturists show the best results. The general fall in physical fitness shown in the table is a criterion of the effects of the various occupations on the physical welfare of the workers. In the London area it was found that respiratory diseases, particularly pulmonary tuberculosis, showed an enormously high percentage in the densely populated districts of the East End. Some curious figures were given by the occupations. Thus, barbers showed the highest percentage with regard to almost every disease. On the other hand, clerks showed comparatively good results, proving that sedentary work, with due outdoor exercise, is not unhealthful. In the London area, 9.9 per cent. of the men were placed in Grades 3 or 4 on account of heart affections, and 3.1 per cent. on account of tuberculosis.

Deaths

Samuel Doty Risley * Philadelphia; University of Pennsylvania, Philadelphia, 1870; aged 75; a veteran of the Civil War; chairman of the Section on Ophthalmology of the American Medical Association in 1893; and a member of the House of Delegates in 1907; president of the American Academy of Medicine, in 1891, of the American Ophthalmological Society in 1907, and of the ophthalmological section of the College of Physicians of Philadelphia, in 1934; lecturer and assistant surgeon in ophthalmology in his alma mater from 1872 to 1879; professor of diseases of the eye, in the Philadelphia Polyclinic from 1886 to 1900 and emeritus professor thereafter; attending surgeon to Will's Eye Hospital, Philadelphia, since 1889; a member of the board of managers of the Pennsylvania Training School for Feeble-Minded; alumni manager of the University of Pennsylvania Hospital since 1896; died, April 1, following a nervous collapse.
